Heberden, widely known for the eponymic "Heberden's nodes," according to Stecher[1] dispelled the notion prevalent up to this time that these bony enlargements were due to gout. The nodes are now regarded as the most benign form of osteoarthritis, readily recognized and characteristic of this general disease. Examination of the hands of some 7,000 unselected persons from Cleveland City Hospital, of visitors to the dispensaries of two general hospitals and of residents in several homes for the aged revealed that the incidence of both the traumatic and the idiopathic (not preceded by trauma) nodes increased with age.[1] The incidence of traumatic nodes was higher in men than in women, higher in manual workers than in physicians and higher in white manual workers than in Negroes. The differences in incidence of traumatic nodes between various groups of white persons seem to depend on differences in exposure of the fingers to trauma. The incidence of idiopathic nodes is universally low before the age of 60, after which it increases rapidly in white women. About one third of white women are affected if they live long. The condition never attains a high proportion in men. A study of hereditary tendency in a group of sixty-eight affected persons revealed that the mothers of affected women were affected twice as often, and the sisters of the affected women three times as often, as would have been expected in the normal population on the basis of chance alone. Apparently heredity plays an important role in the production of Heberden's nodes in these families. The trait appeared to be inherited as a simple dominant; it was probably recessive in men. Stecher did not find evidence that the production of idiopathic Heberden's nodes is influenced by climate, occupation, diet, housing, environment, habits of living, the general state of nutrition or conditions of health. Two conditions appear necessary for the development of idiopathic Heberden's nodes: a hereditary constitution and intact and normally functioning nerve supply to the hand and fingers. Heberden's nodes constitute a particular form of osteoarthritis with characteristics specific for this disease. Studies of the different forms of osteoarthritis may contribute to a greater knowledge of this common affliction,

Woman's Auxiliary

OFFICERS

The national officers and chairmen of standing committees for 1948-1949 of the Woman's Auxiliary to the American Medical Association are as follows:

- President—Mrs. Luther H. Kice, 95 Brook Street, Garden City, Long Island, N. Y.
- President-Elect—Mrs. David B. Allman, 104 St. Charles St., Atlantic City, N. J.
- Vice Presidents:
  - First—Mrs. Ralph Eusden, 4360 Myrtle Ave., Long Beach 7, Calif.
  - Second—Mrs. William W. Potter, 129 Kenesaw Ter., Knoxville, Tenn.
  - Third—Mrs. Lloyd C. Harvie, 417 Ardussi Ave., Saginaw, Mich.
  - Fourth—Mrs. Robert Flanders, North River Road, Manchester, N. H.
- Treasurer—Mrs. Arthur A. Herold, 1166 Louisiana Ave., Shreveport, La.
- Constitutional Sec.—Mrs. George Turner, 3009 Silver St., El Paso, Texas.
- Directors:
  - One year—Mrs. Eustace A. Allen, 18 Collier Road, N. W., Atlanta, Ga.
    - Mrs. I. J. Bridenstine, P. O. Box 1475, Missoula, Montana
    - Mrs. U. G. McClure, 1592 Quarrier St., Charleston 1, W. Va.
    - Mrs. David S. Long, Harrisonville, Mo.
  - Two years—Mrs. James P. Simonds, 234 E. Pearson St., Chicago 11
    - Mrs. Jesse D. Hamer, 1819 N. 11th Ave., Phoenix, Ariz.
    - Mrs. Leo J. Schaefer, 700 Highland, Salina, Kansas
- Chairmen of Standing Committees:
  - Finance—Mrs. Scott C. Applewhite, 240 Bushnell St., San Antonio, Tex.
  - Hygeia—Mrs. Aldace W. Hammond, 214 4th St., Beaver Dam, Wis.
  - Legislation—Mrs. Charles L. Shafer, 219 N. Sprague Ave., Kingston, Pa.
  - Organization—Mrs. Ralph Eusden, 4360 Myrtle Ave., Long Beach 7, Calif.
  - Publications—Mrs. James P. Simonds, 234 E. Pearson St., Chicago 11.
  - Program—Mrs. Harry F. Pohlmann, 29 Railroad Ave., Middletown, N. Y.
  - Public Relations—Mrs. Asher Yaguda, 61 Lincoln Pk., Newark 2, N. J.
  - Revisions—Mrs. Roscoe E. Mosiman, 2686 Magnolia Ave., Seattle 99.
- Special Committee:
  - Reference—Mrs. Rollo K. Packard, 14093 Davana Ter., Sherman Oaks, Calif.
- Historian—Mrs. Jesse P. Hamer, 1819 N. 11th Ave., Phoenix, Ariz.
- Parliamentarian—Mrs. Alfred L. Madden, 44 S. Allen St., Albany, N. Y.

REVISIONS OF BY-LAWS

Revisions of the by-laws, which were presented to the House of Delegates at the twenty-fifth annual meeting in Chicago, June 1948, were adopted as amended. The sections revised will read as follows:

Article VI, Section 6 (constitution)

"To be eligible for election, succession or appointment as president, president-elect, first vice president or director, a member must have served (*a*) as president of the constituent state or territorial auxiliary by virtue of membership in which she is an active member of this Auxiliary, and in addition, (*b*) as an officer or as a chairman of a standing committee, or both, of this Auxiliary for at least two years."

Chapter II, Section 2 (by-laws)

"On the first day of the annual Convention, the Convention shall elect a Nominating Committee of seven members, two of whom shall be from the Board of Directors and five from the Body of Convention members. No more than two members of this Committee shall serve two years consecutively."

Chapter III, Section 3 (president-elect)

Insert between first and second sentences: "She shall serve on all Standing Committees as a member ex officio without the right to vote."

Chapter IV

Section 1—Item 5. Change the word Editorial to Publications; i. e., no. 5 of the Standing Committee will be the Publications Committee, instead of the Editorial Committee.

Section 8—"The Publications Committee shall consist, et cetera."

Chapter V—Official Publication

"The official publications of the Auxiliary shall be the *Bulletin* published by the Woman's Auxiliary to the American Medical Association in which shall be published all official Auxiliary notices and transactions of the Convention and abstracts of the meetings of the Board of Directors, and such other periodicals as are authorized by the Advisory Council to the Woman's Auxiliary."

Chapter VII—Constituent Auxiliaries

"Each constituent auxiliary shall transmit to the Treasurer of this Auxiliary not later than March 15 annually, dues amounting to one dollar for each of its members for the current year, which shall include subscription to the periodicals published by this Auxiliary when authorized by the Advisory Council to the Woman's Auxiliary."

Chapter X—Policy

"All gifts presented to the Woman's Auxiliary must be accepted by the Board of Directors before being announced at the annual meeting."

FUTURE MEETINGS

The twenty-sixth annual meeting of the Woman's Auxiliary to the American Medical Association will be held in Atlantic City, N. J., June 6 to 10, 1949.

The dates of the Conference of State Presidents and Presidents-Elect and the National Chairmen of Standing Committees will be announced as soon as arrangements have been completed.

The registration of the 1948 meeting in Chicago was 841.

Washington Letter

(From Our Regular Correspondent)

July 20, 1948.

Increased Pay for Veterans Professional Personnel

The Veterans Administration announces that about 15,000 physicians, dentists and nurses on its payroll will receive a flat salary increase of $330 annually, retroactive to July 11. The raise was granted in order to give these professional workers, who are exempt from Civil Service provisions, the same treatment accorded other federal employees under the wage increase law enacted recently by Congress. The only Veterans Administration full time doctors to whom the raise will not apply are the relatively few receiving $11,000 or more per annum. Also excepted are member-employees in domiciliary homes, hospital residents, senior cadet nurses in training, part time specialists and consultants in hospitals.

United Mine Workers Extending Rehabilitation of Paraplegic Men

Washington headquarters of United Mine Workers of America disclosed the departure in mid-July of 13 more paraplegic coal miners for rehabilitative care on the West Coast. They entrained at Clarksburg, W. Va., for Permanente Hospital at Vallejo, Calif. Dr. R. R. Sayers, medical advisor of the United Mine Workers Welfare and Retirement Fund, said 75 paraplegic persons are now undergoing physical and vocational rehabilitation in West Coast institutions. To augment Eastern facilities, arrangements have just been completed for use of at least ten beds at the Postgraduate Medical School and Hospital in New York City, said Dr. Sayers. Also participating in the program are the Institute for Rehabilitation and Physical Medicine (New York University) and Lenox Hill Hospital, both in New York City, and the Newark (N. J.) Hospital for Crippled Children.

New Alaskan Medical Expedition Announced

A second medical expedition to Alaska, co-sponsored by the Department of Interior and the American Medical Association, will spend most of August in the Territory. Its members are Drs. John E. Tuhy and W. Charles Martin, of Portland, Ore., and Frank Douglas and David Law (dentist), of Seattle, Wash. The team will give diagnostic and treatment services.

Pan-American Sanitary Bureau Receives Aid

The Pan-American Sanitary Bureau has received a check for $222,000 from Mexico to be applied toward its expanded program of disease control, teaching and medical research in the American republics. Of the sum, $22,000 is Mexico's regular quota payment and the remainder is an extra contribution. Brazil, Argentina and other Latin American countries have voted to make similar contributions, but Mexico's is the first to be received.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

ARIZONA

Workshop in Health and Safety Education.—Arizona's first Workshop in Health and Safety Education will be held at the State Teachers College, Flagstaff, August 2-14. The program is designed to assist teachers, administrators, school nurses and others interested in health and safety education, and to give them an opportunity to discuss such problems with consultants from several sections of the United States. The health education consultants are: Frank S. Stafford, of the United States Office of Education, Washington, D. C.; Dr. William W. Bauer, director, Bureau of Health Education, American Medical Association, Chicago; Miss Vivian Drenckhahn, New York, National Tuberculosis Association; Dr. Henry C. Schumacher, Cleveland, U. S. Public Health Service; Dr. Edith P. Sappington, San Francisco, of the U. S. Children's Bureau, and C. Mayhew Derryberry, Ph.D., San Francisco State College. Many organizations, both state and national, have cooperated in planning and preparing materials for the Workshop, which has become regional in character. Additional information may be obtained from the Registrar, Arizona State College, Flagstaff.

CONNECTICUT

Personal.—Dr. Carl E. Johnson, New Haven, has been appointed a member of the Connecticut Medical Examining Board to succeed Dr. George M. Smith, Pine Orchard, who has resigned after more than twenty-two years of service on the board. Dr. Johnson, a graduate of Harvard Medical School, Boston, 1926, is chief of obstetrics and gynecology at the Hospital of St. Raphael, New Haven, and chairman of the program committee of the state medical society.

First Class in Hospital Administration.—The immediate placement of eight students at the completion of the first year of Yale University's course in hospital administration demonstrates the need for this sort of training, officials of the university have reported. The course at Yale was established in the Department of Public Health with the aid of a grant from the W. K. Kellogg Foundation. Dr. Clement C. Clay, assistant professor of hospital administration, states that only one or two vacancies remain to be filled for the next course starting in September.

ILLINOIS

Dr. Sutton Made Chief of Division.—Dr. Charles F. Sutton has been appointed chief of the Division of Local Health Administration, Illinois Department of Public Health, to succeed Dr. Richard F. Boyd, who accepted a position with the Health and Welfare Fund of the United Mine Workers of America at Washington, D. C. Dr. Sutton, a graduate of Rush Medical College, served in the Army Medical Corps in World War II and has been with the state health department since January 1946.

Chicago

Personal.—Dr. William B. Wartman, Morrison professor of pathology and chairman of the department at Northwestern University Medical School, was recently appointed to the committee on pathology of the division of medical sciences, National Research Council.

Loyola University Receives Millon Dollar Gift.—At the opening of Loyola University's medical-dental school drive June 15 at the Stevens Hotel, the university received a $1,000,000 gift from Frank J. Lewis, Chicago industrialist. Mr. Lewis' gift will be used to establish a trust which is expected to yield $50,000 a year for the medical school's operating expenses. He has also donated the site for the university's proposed Stritch School of Medicine in the West Side Medical Center.

Dr. Saunders Appointed Associate Director.—Dr. H. Prather Saunders, Chicago, was appointed an associate director of the American College of Surgeons, effective June 1. Dr. Saunders joined the staff of the college in March 1946, on his return from duty with the Medical Corps of the Navy. He is a councilor of the Chicago Medical Society, of which he was president in 1942, and a member of the council of the Illinois State Medical Society. He has been a member of the attending surgical staff of Ravenswood Hospital since 1930.

Public Lectures on Radiation.—Six free, public lectures on radiations and radioactive substances in biology and medicine are being given at the University of Chicago at 4:30 p. m. Wednesdays, July 7-August 11 in the Social Science Building (1126 East 59th Street), room 122.

July 7, Raymond E. Zirkle, Ph.D., Significance of Radiosubstances and *High Energy Radiations in Biology and Medicine.*

July 14, William Bloom, Effects of Radiation on the Cells of the Body.

July 21, Robert D. Boche, Ph.D., Effects of Radiation Exposure on Populations.

July 28, J. Garrott Allen, Care of Persons Exposed to Radiation.

August 4, Konrad E. Bloch, Ph.D., Techniques of Using Isotopes as Tracers.

August 11, James W. J. Carpender, Uses of Radioactive Substance in the Treatment of Disease.

INDIANA

Awards for Scholastic Leadership.—The three scholastic leaders in the 1948 Indiana University School of Medicine, , have been awarded medals by the Indiana State Medical Association. The awards this year were a gold medal to Dr. Richard A. Theye, Fort Wayne, now interning at the Indiana University Medical Center; silver medal to Dr. Martin H. Wortzel, Newark, N. J., now interning at Beth Israel Hospital, Newark, and bronze medal to Dr. Max E. Chervin, Philadelphia, intern at Michael Reese Hospital, Chicago.

New Department Heads.—The administrative reorganization program proposed for the Indiana University School of Medicine, Bloomington-Indianapolis, is nearing completion with the appointment of full time heads of the department of surgery and the new department of obstetrics and gynecology. Dr. Harris B. Shumacker Jr. has been appointed chairman of the department of surgery. Dr. Shumacker, formerly associate professor of surgery at Yale University School of Medicine, New Haven, assumed his new post on July 1. Dr. Carl P. Huber, a member of the staff for ten years, has been named chairman of the department of obstetrics and gynecology. The department was created earlier by the merging of the former division of gynecology with the department of obstetrics.

KENTUCKY

Narcotic Violation.—The Bureau of Narcotics, U. S. Treasury Department, reports that Dr. Azzie Z. Tucker, Fulton, pleaded guilty to violation of the federal narcotic code on April 19. His sentence of one year and one day was suspended, and he was placed on probation for three years on condition that he does not apply for registration under the federal narcotic law during the probationary period.

Dr. Underwood Appointed State Health Commissioner.—The State Board of Health of Kentucky has elected Dr. E. Bruce Underwood, Morganfield, state health commissioner and secretary of the state board of health, to succeed the late Dr. Phillip E. Blackerby. Dr. Underwood received his M.D. degree from the University of Louisville School of Medicine in 1937 and was in private practice until 1940. He served as health officer in Union, Webster and Henderson Counties from 1940 to 1946, and in the following year was health officer of Tallahassee, Fla. Since January 1948 he has been in private practice in the clinic which he built at Morganfield.

MISSOURI

State Medical Election.—At the meeting of the state medical association in St. Louis last Spring, Dr. *William A. Bloom*, Fayette, was elected secretary, and Dr. *Charles E. Hyndman*, St. Louis, treasurer, instead of Dr. *Perry W. Jennings*, Canton, who was named as secretary in THE JOURNAL, June 5, 1948, p. 552.

NEW YORK

State Society Selects Education Fund as War Memorial.—The Medical Society of the State of New York voted at its annual meeting in May to establish an education fund for the fifty-eight children of its thirty-two members who died in World War II. On the completion of his secondary school education each child will be given $600 per year if he pursues a collegiate and/or professional postgraduate course up to the age of 25 years if he remains unmarried. The estimated cost of the plan is $244,000. To meet the cost of the War Memorial a special assessment of $12 per member was approved by the house of delegates to be collected by the county societies within the year following the annual meeting. Since the termination of the war the society has been considering various plans for a suitable memorial to its deceased members and voted the educational fund as most appropriate.

New York City

The Romaine Fellowship.—Columbia University College of Physicians and Surgeons has received a bequest of $140,000 for medical research from the estate of the late C. Evaretta Romaine. The fund will be set up as the Dr. DeWitt C. Romaine Fellowship. Dr. Romaine, who died June 1, 1939, graduated from the College of Physicians and Surgeons in 1881.

Personals.—Dr. Frederick L. Liebolt, associate professor of orthopedic surgery, New York Hospital-Cornell University Medical Center, received the honorary doctor of laws degree at the University of Arkansas, Fayetteville, June 5.—Dr. I. Oscar Weissman has been appointed director of Sydenham Hospital, succeeding Dr. Sigmund L. Friedman, who resigned to take a position with the Mount Sinai Hospital, Cleveland. Dr. Weissman, a graduate of Long Island College of Medicine, 1932, has been associated with the U. S. Public Health Service.

Beach Waters Classified.—New York City beaches are being classified by the board of health as follows: Class A, or "approved beach waters" but subject to reclassification in light of continuing observation; class B beaches, "polluted beach waters," and class C, "unsafe beach waters." The records indicate that pollution at some of bathing beaches in the city is increasing and at some beaches may become dangerous for bathing or swimming. The action of the board does not affect that section of the Sanitary Code which forbids the operation of bathing establishments in certain areas, notably the shores of the Hudson, Harlem and East rivers, in Upper New York Bay, Jamaica, Sheepshead and Raritan bays, and parts of Arthur Kill and Kill Van Kull. The Sanitary Code restrictions in those areas continue unchanged.

PENNSYLVANIA

Expand State Society Headquarters.—The Medical Society of the State of Pennsylvania has purchased property adjacent to its present headquarters building in Harrisburg. The three-story building will relieve the present crowded situation and provide for an increase in the activities at the heaquarters of the society, which has grown from 7,230 members enrolled when the present building was purchased in 1922 to 10,200 members.

Philadelphia

Personals.—Dr. Wilbur H. Strickland has been appointed medical director of the Mercy-Douglass Hospital, which was formally merged, by court decree, on March 11. Dr. Seymour S. Kety has been appointed professor of clinical physiology in the Graduate School of Medicine, University of Pennsylvania, effective July 1. Dr. Kety is at present assistant professor of pharmacology, University of Pennsylvania School of Medicine.

Dr. Hubbard to Direct Rheumatic Fever Program.—Dr. John P. Hubbard, Washington, D. C., has been appointed assistant professor of pediatrics at the University of Pennsylvania School of Medicine and will direct a rheumatic fever teaching program throughout Pennsylvania under the auspices of the state health department. Dr. Hubbard's work in rheumatic fever prior to the war, at Harvard Medical School and Children's Hospital, Boston, will continue at the University of Pennsylvania and at Children's Hospital, Philadelphia. He will simultaneously direct a nationwide program of the American Academy of Pediatrics for the improvement of child health from offices in the hospital. Dr. Hubbard has been directing a study of child health services for the academy. He is a graduate of Harvard Medical School, 1931, held a Rockefeller traveling fellowship to study pediatrics and public health in the United States, England and Germany in 1934, was staff physician at St. Lukes Hospital, Tokyo, in 1935, and studied rheumatic fever and heart disease on a Commonwealth Fund research fellowship in 1936-1937 at the House of the Good Samaritan, Boston.

TEXAS

Study of Poliomyelitis.—Columbia University College of Physicians and Surgeons and the Neurological Institute of New York City are cooperating with the University of Texas Medical Branch, Galveston, in a special study of poliomyelitis. Also cooperating is Baylor University College of Medicine, Houston, with Dr. Paul R. Harrington, associate professor of orthopedic surgery, participating. The investigation plans to devise satisfactory criteria for evaluating the neuromuscular status of poliomyelitis in patients. Clinical chemotherapeutic studies will be made with special reference to antibiotics and synthetic compounds which have been shown experimentally to have value against the virus of poliomyelitis. The cooperative research is under the direction of Dr. Murray Sanders, associate professor of bacteriology of the College of Physicians and Surgeons, Dr. Clifford G. Grulee Jr., assistant professor of pediatrics and director of the poliomyelitis unit of the University of Texas Medical Branch, and Dr. Saul R. Korey of the Neurological Institute, New York.

GENERAL

The Original "Cotton Hammer."—At the meeting of the American Association for the Surgery of Trauma in Chicago, June 18, Dr. Kellogg Speed, Chicago, presented to the association the original hammer used by Dr. Frederick J. Cotton, Boston, in the employment of his famous "artificial impaction of the hip" in the treatment of fractures of the neck of the femur. This gavel had placed on it a plate inscribed showing its origin.

Dr. Garrison Wins Cadillac at Meeting.—Dr. Harvey F. Garrison, Jackson, Miss., was the winner of a 1948 Cadillac club coupé presented by White Laboratories, Inc., pharmaceutical manufacturers, at the American Medical Association annual session in Chicago. Dr. Garrison, who operates a children's clinic in Jackson, is past president of the Southern Medical Association and Mississippi State Medical Association. Dr. and Mrs. Garrison cancelled their train reservations in order to drive the new Cadillac home.

Dr. Harrison to Head American Heart Association.—Dr. Tinsley R. Harrison, professor of medicine at Southwestern Medical College, Dallas, Texas, became president of the American Heart Association at its annual meeting in Chicago, June 18-19, succeeding Dr. Arlie R. Barnes, Rochester, Minn. Dr. Harold M. Marvin, New Haven, Conn., former executive secretary of the association, was chosen president-elect. Dr. Harrison is a graduate of Johns Hopkins University School of Medicine, Baltimore, 1922, and has been at Southwestern Medical College since 1944.

Dr. Brick Wins Essay Contest.—Dr. Irving B. Brick, Georgetown University School of Medicine, Washington, D. C., won the eighth annual essay contest of the Mississippi Valley Medical Society "for the best unpublished essay on a subject of practical and applicable value to the general practitioner." His paper is entitled "Clinical Significance of Hiatus Hernia." Second prize goes to Dr. Franklin I. Shroyer, Dayton, Ohio, for his essay, "Cytological Diagnosis of Abnormal Growth in the Female Pelvis." Dr. Brick will receive a cash award and a gold medal. He will present his essay at the thirteenth annual meeting of the Mississippi Valley Medical Society in Springfield, Ill., September 29-October 1.

Traffic Deaths Rise in May.—The National Safety Council reports that traffic deaths went up in May, the first time in seven months, with an increase of 3 per cent over May of last year. The May death toll of 2,650 brought the year's total to 11,270, 5 per cent less than the 11,830 killed in the first five months of 1947. The Mountain states were chiefly responsible for the May increase with a 25 per cent jump in fatalities; Atlantic states had sharp increases also, while the Central states held even. Pacific states were the only ones to continue improvement. Although travel figures for May are not yet available, the council believes that a heavy increase in mileage may have been responsible for the rise.

Communicable Diseases.—The U. S. Public Health Service reports that the week ending July 3 was the sixth consecutive week in which no case of smallpox had been reported in the United States. For the week ending July 3, 29 cases of Rocky Mountain spotted fever were reported of which only 6 were in the Mountain States. Of 38 states reporting on rabies in animals, 21 reported no cases and of 17 states reporting cases the largest numbers were in Indiana (20), Texas (14), Michigan (10), Kentucky (8), and New York, Ohio, Florida and California (7 each). One case of anthrax was reported in each of the following states: New York, New Jersey and Pennsylvania, bringing the total to date to 38 cases, as compared with 28 of the corresponding period of last year.

Poliomyelitis Incidence.—The National Foundation for Infantile Paralysis reports high incidence of poliomyelitis for the four weeks ending June 12, during which 644 cases were reported throughout the country. Total for the first twenty-four weeks of 1948 was 1,446 cases reported, compared with 1,047 for the comparable period last year. Outbreaks continued in Texas, with 427 cases to June 12; North Carolina, 148 cases; Iowa, 58, and South Dakota, 21. Other states showing an increase in cases over the same period in 1947 include Indiana, with 28 as compared with 18 last year; Iowa, 52 against 14; New Jersey, 31 against 13; Oregon, 20 against 8; South Carolina, 13 against 4; Washington, 28 against 15; North Dakota, 110 against 18, and South Dakota, 21 against 2.

Cardiological Congress.—At the recent meeting of the Third Interamerican Cardiological Congress, Dr. Louis N. Katz, Chicago, was made permanent honorary president of the Interamerican Society of Cardiology. It was agreed that the Fourth Interamerican Cardiological Congress would be held in Buenos Aires in 1952. The First International Cardiological Congress will be held at some as yet undetermined place in Europe in 1950. Registration for the congress was 520 representing 170 active members and delegates and thirty-six countries. The proceedings and abstracts are to be published in the *American Heart Journal, Belgium Acta Cardiologica, Revista Argentina de Cardiologia* and *Archivas del Instituto de Cardiologia de México.*

The American Congress of Physical Medicine.—This organization will hold its twenty-sixth annual session September 7-11 at the Hotel Statler, Washington, D. C. All sessions will be open to members of the medical profession in good standing. In addition to the scientific sessions, the annual instruction courses will be held September 7-10. These courses will be offered in two groups: One set of ten lectures will be based primarily on physics and physiology and attendance will be limited to physicians; one set of ten lectures will be more general in character and will be open to physicians as well as to physical therapists. The physical therapists must be registered with the American Registry of Physical Therapy Technicians. Information may be obtained by writing to the American Congress of Physical Medicine, 30 North Michigan Avenue, Chicago 2.

Research Program on Human Reproduction.—The directors of the National Committee on Maternal Health have approved five applications for research in human reproduction made by the National Research Council. Grants total $21,918 for the first year. Scientists in charge of these studies and the titles of their research are: David W. Bishop, Ph.D., assistant professor of zoology, University of Illinois, Chicago—(1) radioactive phosphorus turnover in sperm; (2) effect of aging of sperm in male tract on oxygen consumption and glycolysis; G. E. Seegar Jones, instructor in gynecology, Johns Hopkins University School of Medicine, Baltimore—role of thyroid function in human reproduction; effect of thiouracil on the reproductive rate in rats; role of thyroid function in the human fetus; Doris H. Phelps, Ph.D., research associate, Vanderbilt University, Nashville, Tenn., who will conduct her project at the University of Witwatersrand, Johannesburg, South Africa—studies on endometrial vascular phenomena; Gregory Pincus, Sc.D., director of laboratories, Foundation for Experimental Biology, Worcester, Mass.—control of fertilization and of the early development of mammalian eggs; Boris B. Rubenstein, Michael Reese Hospital, Chicago—penetration and survival of sperm in the female genital tract.

The Arthritis and Rheumatism Foundation.—Dr. W. Paul Holbrook, Tucson, Ariz., has announced the formation of a foundation to promote the study of arthritis and other rheumatic conditions. The new foundation is sponsored by the American Rheumatism Association in cooperation with the National Arthritis Research Foundation, the Detroit Fund for Crippling Diseases, and others. Seven and one-half million persons in the United States are estimated to be afflicted with arthritis or related disorders. The medical policies and activities of the new foundation will be under the direction of a medical and scientific committee now being organized. The chairman of the board of directors is Floyd B. Odlum, Indio, Calif., president of the Atlas Corporation. The main objectives of the new foundation include a nationwide survey of what can be done to combat arthritis. It expects to: (1) develop, with the aid of the National Research Council, a research program designed to mobilize facilities of the nation's medical schools and of the basic sciences, in the search to discover the cause and methods for the prevention and cure of rheumatic diseases; (2) establish fellowships designed to increase the number of men qualified to conduct research and to specialize in the treatment of these diseases; (3) develop key centers throughout the country devoted to research, teaching and treatment, coordinated with medical schools; (4) promote a program of medical education to increase the appreciation of the profession as a whole of what can and should be done to bring effective treatment to patients with rheumatism; (5) foster the development throughout the nation of more adequate provision for patients with rheumatism, particularly in connection with the work of general hospital. Thirty-eight local chapters of the foundation will cover the entire nation. Chapters also will help integrate programs of investigation within their areas as well as raise funds for the purpose of financing such local programs and providing an equitable share of the funds needed to promote the national program of research as well as general educational and planning activities designed to support and increase the effectiveness of local efforts. In addition to Mr. Odlum and Dr. Holbrook, the president, the board of directors of the new foundation are:

Mr. Cyril H. Jones, Shelburne, Vt., former head of the Milton (Mass.) Academy, vice chairman and vice-president.

Mr. Hayden N. Smith, New York, member of the firm of Winthrop, Stimson, Putnam and Roberts, secretary.

Mr. James G. Blaine, New York, president, Marine Midland Trust Company of New York, treasurer.

Mr. David G. Baird, New York, of the insurance firm of Marsh and McLennan.

Dr. Walter Bauer, Boston, director of the Robert M. Lovett Foundation for Crippling Diseases and associate professor of medicine, Harvard University.

Dr. Ralph Boots, New York, director of the Edward Daniels Falkner Arthritis Clinic at Presbyterian Hospital and professor of clinical medicine, Columbia University College of Physicians and Surgeons.

Mr. A. B. Frey, St. Louis, attorney, and president of the National Arthritis Research Foundation.

Dr. Richard H. Freyberg, New York, associate professor of clinical medicine, Cornell University Medical College, and president of the American Rheumatism Association.

Mr. George L. Harrison, New York, chairman of the Board of New York Life Insurance Company.

Mr. H. J. McLaurin, Detroit, president of G. M. Underwriters, Inc. and general agent of Aetna Life Insurance Company, and trustee of the Detroit Fund for Crippling Diseases.

Mr. Frank Mandel, Chicago, Mandel Bros. Department Store.

Mr. Richard S. Reynolds, Richmond, Va., president of Reynolds Metal Company.

Dr. Charley J. Smythe, Plymouth, Mich., medical director, William J. Seymour Hospital, Eloise, Mich.

Dr. Robert M. Stecher, Cleveland, past president of American Rheumatism Association.

Mr. Howell Van Auken, Detroit, member of the law firm of Lucking, Van Auken, Schumann and Greiner, and trustee of The Detroit Fund for Crippling Diseases.

Mr. Charles B. Wrightsman, Houston, Texas, president, The Standard Oil Company of Kansas.

FOREIGN

France

International Congress on Sulfur.—This Congress will be held in Cauterets (High Pyrenees), France, September 13-15, under the patronage of the Minister of Public Health. Subjects to be reported include sulfur and the life of the cell, the detoxicating effect of sulfur, and sulfur deficiencies. In the medical section sulfur will be discussed in relation to endocrine glands, respiratory apparatus, voice, skin, liver, rheumatism, study of metabolism of sulfur in the organism, pyretotherapy with sulfur, arteries and nutrition.

Hungary

Hungarian Congress of Pediatrics.—The pediatric section of the Hungarian Medical Trade Union is organizing an International Congress of Pediatrics to be held in Budapest September 4-12. Two days of the congress will be devoted to plenary sessions of all the sections. Rheumatic fever, toxicosis and social significance and results of pediatrics will be discussed. All pediatricians are invited to participate, and those who wish to attend should communicate with the Centenary Congress Committee, Bokay Janos u. 53, Budapest 8, Hungary. Those desiring to take part in the discussion or to present a paper are requested to give the title and a short summary of the lecture.

CORRECTIONS

Graduate Course in Endocrinology.—In the list of graduate courses in Endocrinology in the June 19, 1948, Journal, page 726, the date for the course sponsored by the American College of Physicians should have been November 1-6 instead of November 8-13. This course will be given at the LaSalle Hotel, Chicago.

Carcinoma of the Uterus, Ovary and Tube.—In the article by this title by Dr. Norman F. Miller in The Journal, Jan. 17, 1948, page 165, the last figure in column 3 of table 2 should be 23 instead of 36 and the last figure in column 5 of table 2 should be 9 instead of 12.

Dexedrine.—In The Journal, June 19, 1948, page 756, in reply to a query concerning "dexedrine," it was erroneously stated that "dexedrine" is the same substance as d-desoxyephedrine. "Dexedrine" is not d-desoxyephedrine. It is the dextrorotary isomer of amphetamine: 1-phenyl-2-amino-propane. There appears to be considerable confusion between these two drugs, doubtless due in part to the fact that they are related in chemical structure and are both dextrorotary.

Deaths

George Van Ingen Brown ⊕ Milwaukee, died at St. Mary's Hospital April 2, aged 86, of carcinoma of the prostate. Dr. Brown was born in St. Paul on Jan. 15, 1862. He graduated from the Pennsylvania College of Dental Surgery, Philadelphia, in 1881, and from the Milwaukee Medical College in 1895. He practiced dentistry in St. Paul and Duluth from 1881 to 1898, then became professor of operative dentistry and oral surgery and dean of the dental department at Milwaukee Medical College. He was a special lecturer on oral surgery in the dental department at the University of Illinois, 1902-1903, State University of Iowa, 1903-1904, University of Tennessee in 1904, Vanderbilt University in 1905 and the Southern Dental College in Atlanta from 1909 to 1915. From 1904 to 1910 he was professor of oral surgery and pathology at the State University of Iowa. Dr. Brown was professor of oral and plastic surgery at the University of Wisconsin Medical School, Madison, from 1920 until he retired as emeritus professor in 1937. From 1915 to 1919 he served as first lieutenant, captain, major and lieutenant colonel in the medical reserve corps. During World War I he served in the Surgeon General's Office in Washington, in charge of the section of plastic and oral surgery; later he was in charge of plastic and oral surgery at General Hospital number 11, Cape May, N. J., and chief of the maxillofacial service at Walter Reed Hospital, Washington, D. C. In 1919 he was appointed surgeon in the U. S. Public Health Service and consultant in plastic surgery for the Bureau of War Risk Insurance. He was past president of the Milwaukee Academy of Medicine, Milwaukee Surgical Society and the Inter-State Post-Graduate Medical Association of North America. He was a member of the Pan American Medical Association, the Society of Plastic and Reconstructive Surgery, Société Scientifique Française de Chirurgie Reparatrice, Plastique et Esthetique, Paris, France, and honorary member of the La Societé Belge de Stomatologie and the Italian Physico-Chemical Academy of Palermo, Italy, a fellow of the American College of Surgeons and a specialist certified by the American Board of Plastic Surgery. In 1903 he was appointed as a delegate to the International Medical Congress in Madrid, Spain, and in 1911 was appointed to report on harelip and cleft palate before the International Medical Congress in Budapest. He served as secretary of the Section on Stomatology of the American Medical Association in 1897 and 1898 and from 1921 to 1924, and as chairman in 1898 and 1899 and member of the House of Delegates in 1902, 1907 and from 1909 through 1916. Dr. Brown was on the staffs of the Milwaukee County Hospital in Wauwatosa, State of Wisconsin General Hospital, Wisconsin Methodist Hospital, Wisconsin Orthopedic Hospital for Children and Madison General Hospital all in Madison, Veterans Administration Hospital in Wood, Columbia, Milwaukee Children's and St. Mary's hospitals in Milwaukee. In 1935 he was honored by the Boy Scouts with a silver beaver award, highest scouting award, for his services, and in 1938 was elected a member of the National Boy Scout Council, serving in that post until his death. Dr. Brown was the author of four editions of "Surgery of Oral and Facial Diseases and Malformations, Their Diagnosis and Treatment Including Plastic Surgical Reconstruction" and contributor to "The Cyclopedia of Medicine" and other publications.

Henricus Johannes Stander ⊕ New York; born in Georgetown, Cape Colony, South Africa, June 21, 1894; Yale University School of Medicine, New Haven, 1921; professor of obstetrics and gynecology at the Cornell University Medical College; formerly associate professor of obstetrics at the Johns Hopkins University School of Medicine, Baltimore; specialist certified by the American Board of Obstetrics and Gynecology; member of the school board of Scarsdale; member of the American Gynecological Society, of which he had been vice president, and New York Obstetrical Society; fellow of the American College of Surgeons; in 1937 received the Order of Merit of Carlos Finlay in recognition of his services to Cuba; in 1947 received honorary M.D. degree from Trinity College, Dublin University; obstetrician and gynecologist in chief to the New York Hospital; author of "Toxemias of Pregnancy" 1929, "Williams Obstetrics" in 1936 and 1941, and "A Textbook of Obstetrics," 1945; died in Scarsdale, N. Y., May 2, aged 53, of coronary disease.

Alois Bachman Graham ⊕ Ligonier, Pa.; born in Madison, Ind., Sept. 27, 1870; Medical College of Indiana, Indianapolis, 1894; professor emeritus of surgery (proctology) at the Indiana University School of Medicine, Indianapolis; president of the Seventh District (Ind.) Medical Society in 1913, the Indianapolis Medical Society in 1916, the American Proctologic Society in 1919 and the Indiana State Medical Association in 1931, of which he was a member; member of the House of Delegates of the American Medical Association in 1920 and 1921, and chairman of the Section on Gastro-Enterology and Proctology in 1928 and 1929; fellow of the American College of Surgeons; chief of the surgical staff of Base Hospital number 32 in France during World War I, serving for eighteen months in the medical corps; formerly on the staff of City Hospital; died in St. Margaret Memorial Hospital, Pittsburgh, April 5, aged 77.

John Tolson O'Ferrall ⊕ New Orleans; born in Meridian, Miss., Aug. 18, 1885; Medical Department of Tulane University of Louisiana, New Orleans, 1908; specialist certified by the American Board of Orthopaedic Surgery, Inc.; member of the Clinical Orthopaedic Society, Southeastern Surgical Congress and the American Academy of Orthopaedic Surgeons; formerly vice president of the Louisiana State Medical Society; fellow of the American College of Surgeons; served overseas during World War I; affiliated with the New Orleans Hospital and Dispensary for Women and Children, Lakeshore Hospital and the Southern Baptist Hospital, where he died recently, aged 62, of pneumonia.

Addison Carey Page ⊕ Des Moines; born in New Sharon, Iowa, in 1874; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1898; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; served as treasurer of the Iowa State Medical Society; past president of the Polk County Medical Society; from 1939 to 1945 member of the advisory state board of health; formerly on the faculty of the Drake University Medical Department; on the staffs of the Iowa Methodist and Iowa Lutheran hospitals; died in Mason City, Iowa, April 14, aged 73, of coronary disease.

Clifford Wilmot Mack ⊕ Livermore, Calif.; born in Rawden, Ont., Canada, Dec. 16, 1884; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1908; specialist certified by the American Board of Psychiatry and Neurology, Inc.; fellow of the American College of Physicians; member of the American Psychiatric Association; past president of the Alameda County Medical Association; served during World War I; consulting psychiatrist to the Samuel Merritt Hospital in Oakland and the Veterans Administration Hospital; medical superintendent of the Livermore Sanitarium; died March 31, aged 63, of coronary occlusion.

Thomas Ritchie Ponton, Yucaipa, Calif.; Manitoba Medical College, Winnipeg, Man., Canada, 1898; served as superintendent of the Hollywood Hospital in Hollywood, Calif., Illinois Masonic Hospital in Chicago and the University Hospital in Augusta, Ga.; at one time medical superintendent of the Vancouver General Hospital in Vancouver, B. C.; served with the Canadian Army during World War I; for many years editor and at the time of his death consulting editor of *Hospital Management;* died in Redlands April 2, aged 73, of cerebral hemorrhage.

Carles Harth Able, Norway, S. C.; University of Georgia Medical Department, Augusta, 1884; died March 28, aged 89.

Emil Amberg ⊕ Detroit; Universität Heidelberg Medizinische Fakultät, Baden, Germany, 1894; member of the American Academy of Ophthalmology and Otolaryngology, and the American Otological Society, Inc.; fellow of the American College of Surgeons; specialist certified by the American Board of Otolaryngology; consulting otologist at Grace Hospital and on the adjunct staff of Harper Hospital, where he died April 12, aged 79, of cerebral hemorrhage.

Edmund James Barnes ⊕ Ossining, N. Y.; University and Bellevue Hospital Medical College, New York, 1909; served during World War I; died in Ossining Hospital March 23, aged 71, of perforated gastric ulcer and peritonitis.

Delbert Barney, Wilkes-Barre, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1887; member of the American Medical Association; past president and secretary of the Luzerne County Medical Society; served on the staff of Wilkes-Barre General Hospital; died March 20, aged 88, of acute congestive heart failure.

Joseph Baum, Woodmere, N. Y.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1893; member of the American Medical Association; formerly consulting physician for the New York Board of Health; affiliated with St. Joseph's Hospital in Far Rockaway, where he was vice president of the Rockaway Savings Bank; died April 8, aged 78, of bronchopneumonia.

Louis Charles Benkert, Columbus, Ohio; Ohio Medical University, Columbus, 1897; formerly county coroner, police surgeon and physician for the Ohio Penitentiary; served on the board of education, of which he was president from 1915 to 1922; died April 4, aged 74, of cardiovascular disease.

Edward Percy Beverley ⊕ Lieutenant Colonel, U. S. Army, retired, Broad Run, Va.; University of the South Medical Department, Sewanee, Tenn., 1899; also a graduate in pharmacy; served during World War I; entered the medical corps of the U. S. Army as a major on Dec. 2, 1920; retired Aug. 31, 1937 for disability in line of duty; died in the Walter Reed General Hospital, Washington, D. C., April 3, aged 72, of coronary thrombosis.

Mary Euphrasia Smith Briggs, Pawtucket, R. I.; Tufts College Medical School, Boston, 1894; died March 9, aged 84.

Theodore Prewitt Brookes ⊕ St. Louis; Washington University School of Medicine, St. Louis, 1909; assistant professor of clinical orthopedic surgery at his alma mater; member of the American Academy of Orthopedic Surgeons; fellow of the American College of Surgeons; affiliated with the Evangelical Deaconess Home and Hospital, Barnes, St. Louis Children's and St. Louis Maternity hospitals; on the consulting orthopedic staff of the Lutheran Hospital, where he died April 1, aged 61, of cerebral thrombosis.

George Davies Chunn ⊕ Colonel, U. S. Army, retired, Sarasota, Fla.; Johns Hopkins University School of Medicine, Baltimore, 1913; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; entered the medical corps of the U. S. Army in 1915 and retired Oct. 31, 1945; died in Tampa March 12, aged 59, of carcinoma of the prostate.

Frank Benjamin Converse ⊕ West Willington, Conn. (licensed in Connecticut in 1894); past president of the Tolland County Medical Society; for three terms state representative; served as health officer; president of the medical staff of Johnson Memorial Hospital in Stafford Springs; died April 4, aged 82, of arteriosclerotic heart disease.

Joseph Stanley Cutler ⊕ Wauwatosa, Wis.; Chicago Medical College, 1890; for many years health officer; served during World War I; affiliated with the Milwaukee County Hospital; died recently, aged 82, of chronic nephritis and pernicious anemia.

James Ernest Davis, St. Petersburg, Fla. (licensed in Florida in 1920); died March 19, aged 72.

Carl Vinton Davisson ⊕ Williamsport, Ind.; Indiana University School of Medicine, Indianapolis, 1908; medical examiner for the county draft board and later an officer in the medical corps of the U. S. Army during World War I; served on the staffs of Lafayette Home Hospital and St. Elizabeth Hospital, Lafayette, where he died April 7, aged 67, of carcinoma of the pancreas.

S. James Deehan II, Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1940; member of the American Medical Association; served during World War II; interned at the Memorial Hospital, where he served a residency; died April 6, aged 36.

Ernest Adolphus Dennard, Fort Smith, Ark.; Meharry Medical College, Nashville, Tenn., 1914; died April 1, aged 62, of coronary embolus.

Albert Eugene Dietrich, Bay Shore, N. Y.; Long Island College Hospital, Brooklyn, 1893; died March 23, aged 79, of neuritis.

Cova Roy Graham, Bourbon, Ind.; University of Louisville (Ky.) Medical Department, 1910; member of the American Medical Association; past president of the Marshall County Medical Society; died April 3, aged 62, of coronary occlusion.

Stilwell G. Meany ⊕ East Troy, Wis.; Marquette University School of Medicine, Milwaukee, 1913; for many years president of the school board; on the staff of Walworth County Hospital in Elkhorn; died April 4, aged 57, of coronary sclerosis.

Harry Lewington Merryday ⊕ Daytona Beach, Fla.; University of Louisville School of Medicine, 1914; past president of the Volusia County Medical Society; member of the Selective Service Advisory Board during World War II; member and past chief of staff of the Halifax District Hospital; past director of the chamber of commerce; died in the Riverside Hospital, Jacksonville, March 28, aged 63, of heart disease.

Lillian Morgans, Middletown, N. Y.; New York Medical College and Hospital for Women, Homeopathic, New York, 1906; died April 7, aged 76, of coronary thrombosis.

Charles W. Morrow, Fairhope, Ala.; University of Maryland School of Medicine, Baltimore, 1888; died March 25, aged 81.

Frederic T. Murlless Jr., Hartford, Conn. (licensed in Connecticut in 1892); also a dentist; died March 11, aged 81.

Edward Henry Nelson ⊕ Chisholm, Minn.; Minneapolis College of Physicians and Surgeons, medical department of Hamline University, 1903; served as mayor of Chisholm and as member of the board of education; died in Hibbing General Hospital, Hibbing, March 29, aged 72, of cerebral embolism.

Arthur North, Corpus Christi, Texas; University of Arkansas School of Medicine, Little Rock, 1907; member of the American Medical Association; served as a physician for the U. S. Department of Justice and the county jail; member of the local draft board during World Wars I and II; died March 13, aged 75, of cardiac decompensation.

John Gabriel O'Connell, Bridgeport, Conn.; Tufts College Medical School, Boston, 1917; member of the American Medical Association; formerly associate surgeon at Bridgeport Hospital; died in Newington, April 6, aged 57, of coronary thrombosis.

Herbert James Orchard ⊕ Superior, Wis.; Trinity Medical College, Toronto, Canada, 1892; formerly city health officer; for many years affiliated with St. Mary's Hospital, died March 25, aged 79, of arteriosclerotic heart disease and bronchiectasis.

Harry Walker Paul ⊕ Shreveport, La.; University of Texas School of Medicine, Galveston, 1920; deputy coroner of Caddo Parish for many years; on the staffs of the T. E. Schumpert Memorial Sanitarium and the North Louisiana Sanitarium; died in Tri-State Hospital March 22, aged 53, of pulmonary infarct and cirrhosis of the liver.

Birdsey Preston Peck, Eaton, Colo.; Denver Homeopathic College, 1904; died in March, aged 73.

Wilson Pendleton, Asheville, N. C.; University of Virginia Department of Medicine, Charlottesville, 1908; member of the American Medical Association; past president of the Buncombe County Medical Society; member of the American College of Chest Physicians; served during World War I; affiliated with the Asheville Mission Hospital; died March 28, aged 62, of cerebral hemorrhage.

Valentine Simmons; Pacific Palisades, Calif.; Medical Department of Tulane University of Louisiana, New Orleans, 1897; member of the American Medical Association and of the Louisiana State Medical Society; died March 24, aged 76, of carcinoma.

Leigh Arthur Simpson, Fulton, N. Y.; Syracuse University College of Medicine, 1920; member of the American Medical Association; died March 26, aged 52, of coronary thrombosis.

Hiram Jason Smith ⊕ Chicago; born in Oakfield, Wis., in 1882; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1907; clinical associate professor of ophthalmology at his alma mater; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology; chief oculist for the Illinois Central Railroad; affiliated with Illinois Central Hospital, where he died February 16, aged 65, of uremia.

Winfield Scott Smith, Philippi, W. Va.; University of the South Medical Department, Sewanee, Tenn.; 1898; served as health officer for Barbour County and as examiner for the local Selective Service board during World War I; died March 24, aged 74, of coronary occlusion.

Thomas Millette Snyder, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1916; professor of histology and embryology and clinical professor of ophthalmology at his alma mater; on the staff of the Hahnemann Hospital, where he died March 25, aged 54.

Arthur Jay Somers ⊕ Chippewa Falls, Wis.; Milwaukee Medical College, 1905; affiliated with St. Joseph's Hospital, where he died March 25, aged 69, of uremia.

Joseph Anderson Speed, Durham, N. C.; Jefferson Medical College of Philadelphia, 1914; member of the American Medical Association; died March 15, aged 59.

George William Stark ⊕ Syracuse, N. Y.; Syracuse University College of Medicine, 1907; member of the American Urological Association; died in Syracuse General Hospital March 2, aged 65, of coronary thrombosis.

Francis Lansing Stebbins, Geneva, N. Y.; University of the City of New York Medical Department, New York, 1891; member of the original staff of the Geneva (N. Y.) General Hospital; died in the Clifton Springs (N. Y.) Sanitarium, March 27, aged 81, of arteriosclerosis and pulmonary edema.

Henry Danford Steele, Princeton, Ill.; Northwestern University Medical School, Chicago, 1892; member of the American Medical Association; died in Phoenix, Ariz., March 3, aged 78, of coronary thrombosis.

John Frank Stein ⊕ Oshkosh, Wis.; Milwaukee Medical College, 1905; served overseas during World War I; for many years on the staff of Mercy Hospital, where he died March aged 66, of septicemia due to an infected gallbladder.

Payment of Specialists in National Health Service

It is estimated that the new National Health Service will cost annually $562,400,000 and its ancillary services $480,000,000. Admitting this staggering cost, a member of the Government claimed its worth in the saving of human life and suffering which it would bring about. Meanwhile the Government goes ahead with details of its gigantic scheme for the socialization of medicine. The total maximum fees for a specialist physician or surgeon holding a part time appointment will be $8,000 a year, which will be made up as follows: For hospital work specialists will be paid $800 a year for a half-day session a week at a hospital or clinic, not more than eight sessions a week being allowed. Consultations in the patient's home to which a specialist is called by a general practitioner will be paid for at the rate of $400 a quarter for twenty-five consultations. No fee will be paid for consultations in excess of twenty-five. Major operations will be performed by surgeons in the sessional time. For minor operations at the patient's home the specialist will be paid $21. For full time specialists rates of pay ranging from $6,000 to $20,000 have been recommended by a committee appointed by the Government. All varieties of specialists will be remunerated on the same scale, the place of an individual within the scale being dependent on his responsibilities, experience and skill. Consideration was also given to the view that in the hospital system of the future there should be a more uniform level of efficiency throughout the country, a better distribution of specialists and permeation throughout the hospital service of every region of the influence of the university center. These objects could be achieved only by increasing the mobility of specialists throughout the service and facilitating the exchange of staffs between teaching and nonteaching hospitals. The starting salaries recommended for specialists appointed to the staffs of hospitals are: at 32 years of age $6,000; at 30 or below, $5,000; at 31, $5,500; above 32, $6,000, with, at the discretion of the authorities, up to four special increments of $500 in respect of age, special experience and qualifications. The initial salary should be augmented by an additional $500 after each year of service until $10,000 is reached. A national committee, predominantly professional in composition, should be established to select individual specialists whose outstanding distinction merited higher reward, and should confer awards in three grades as recognition of special contributions to medicine, exceptional ability or outstanding professional work. It is also recommended that practitioners in training for special branches should receive salaries.

Code to Control the Advertising of Nostrums

The exaggerated, if not entirely fictitious, claims made for proprietary medicines are such a scandal that a code for the guidance of advertisers, manufacturers, distributors and publishers has been drafted by organizations representing these interests. It is recommended that advertisements should not contain a claim to cure any ailment or symptoms of ill health, or any offer or advice relating to the treatment or serious diseases that should rightly claim medical attention, or make misleading or exaggerated claims. There should be no offer to return money. Terms such as college, clinic, institute or laboratory should not be used unless an establishment corresponding with the description exists. For products offered to women there should be no use of terms such as "never known to fail." References to doctors or hospitals, whether British or foreign, are not permissible unless they can be substantiated. Special claims that certain drugs have special qualities that are unknown are prohibited, as is the use of terms implying treatments for sexual weakness, premature aging or impaired vitality. A long list is given of diseases for which treatment should not be advertised. It includes alopecia, amenorrhea, arteriosclerosis, baldness, high or low blood pressure, convulsions, dermatitis, disseminated sclerosis, structural or organic defects of the ears or eyes, fungous infections, gallstones, goiter, heart troubles, impetigo, indigestion, insomnia, leg troubles, lupus, menopausal ailments, pyorrhea, renal disease, rheumatism, ringworm and gastric and duodenal ulcer.

Attempt by the Government to Establish Free Medicines in Australia

Unlike New Zealand, the government scheme for a state medical service has been defeated in Australia by the medical profession. But having failed to provide free treatment, the government is trying to provide free medicines, which again is opposed by the medical profession. The federal council of the Australian British Medical Association has instructed its members to return all formularies and prescription forms for free medicine sent to them by the government, and to continue to prescribe on private forms which will not enable patients to receive free medicines. Doctors are advised to send to their patients a circular explaining that they must be at liberty to prescribe what they think best and not the mixture that the government thinks best. This boycott follows four years of fruitless negotiation. The government's case for restricting the medicines to be supplied free is that unlimited prescribing would require unlimited expenditure.

PARIS

Conference on Nomenclature

At the end of the nineteenth century, France, acting under Bertillon's influence, convened an international conference on nomenclature of diseases and the causes of death. It was agreed that this nomenclature would be revised every tenth year. In November 1946, the temporary Commission of the World Health Organization created an International Committee of Experts of 9 members, each representing a nation, entrusted with the preparation of the sixth decennial revision of the nomenclature. This conference met in Paris, April 26-30, 1948, under the presidency of Professor Baudouin. Delegates from thirty nations were present.

At this meeting the delegates signed an agreement by which international statistical classification of diseases, traumas and causes of death will be submitted to the World Health Organization for investigation and action. Countries that took no part in the conference will be able to join on application. The new classification comprises nine hundred and fifty-two items covering disease, morbid conditions and exogenous causes of morbidity and mortality. It constitutes the last to be compulsorily used for the coding of medical cards and death certificates; moreover, several abbreviated lists are proposed to meet certain requirements, such as a form for death certificates, and a ruling for the selection of the initial cause of death. The new statistical classification will come into force Jan. 1, 1950. The new classification shows remarkable progress in comparison with the classification of 1938. The number of items has been increased from two hundred to nine hundred and fifty-two and, for the first time, includes not only causes of death but all causes of disease.

The conference submitted to the World Health Organization the following proposals: (1) constitution of a permanent Committee of Experts in Sanitary Statistics, (2) constitution by various governments of National Committees, the duties of which it would be to coordinate statistical works within the country and to serve as a liaison unit between the medico-statistical organizations and the Committee of Experts of the

World Health Organization, (3) decentralization of the study of certain problems, which would be entrusted to National Committees, and (4) convocation, when needed, of international conferences on statistical problems and cooperation with the interested sections of the United Nations.

Superannuation Pension for Physicians

The law of Jan. 17, 1948, provides for a compulsory basic pension at least equal to half of the superannuated workers' pension. This modest grant is a result of the creation of the "Liberal Professions Fund." The law provides for a supplementary pension, created on the application of the interested profession. The autonomous physicians' fund will be the concern of physicians only and will be managed by physicians without being submitted to any other professional fund. The National Council of the Order of Doctors has had a pension established, which would be payable after the age of 65, provided that the beneficiary stops practicing; it can be deferred as long as the interested physician desires. The plan provides for the payment of 200,000 francs to lawful legatees in case the physician dies before 65, the reversibility of half the pension to the widow when she attains the age of 65 and in case of total disability the payment of 200,000 francs and of the whole pension. It is estimated that one physician out of two will retire at 65. A reduction of the yearly contribution by young and aged physicians is provided. The grant of the pension to physicians who have attained the age of 65 and who have not made the necessary annual payments will be made against payment by them of a lump sum, covering partially the lacking payments. The plan has just been submitted to all physicians of France for referendum.

PALESTINE

(From Our Regular Correspondent)

JERUSALEM, May 17, 1948.

Palestine Disturbances after November 29, 1947

When the United Nations General Assembly made known its decision to partition Palestine, an uninterrupted wave of war began in this country. In the first five months there was a total casualty toll of 10,646 persons, 5,014 of whom were reported killed and 5,632 wounded. Of the 5,014 dead, 1,256 were Jews, 3,569 Arabs; the rest included military personnel and police. Of the 5,632 wounded, 2,102 were Jews and 3,163 Arabs. As illustrated by these figures, the endeavors of the Palestine government to maintain law and order have, unfortunately, proved ineffective. In January 1948 the Palestine government approached the International Red Cross with the request to send a mission to Palestine which should examine the situation in the light of the many casualties and the difficulties of hospitalization. At the end of January, three delegates of the International Red Cross were elected: Dr. R. Marti, Dr. M. J. de Reynier, both of the International Red Cross Headquarters in Geneva, and Dr. N. I. Munier of Egypt, head of the Middle East International Red Cross Mission. The commission made a tour through Palestine, had discussions with the responsible authorities of the Jews (Vaad Le'umi, Dr. Katznelson, and the Red Shield Organization, Dr. Nissel, Dr. Dankwert and Dr. Levontin), as well as with the Arab Medical Association, and inspected the available medical institutes and hospitals. The commission also visited the Department of Contagious Diseases of the Government Hospital at Beit Safafa, where on Dec. 28, 1947, the Jewish chief, Dr. H. Lehrs, was murdered in cold blood while on his daily round of duty. Inspecting Jaffa, Tel-Aviv and Haifa, the International Red Cross Commission saw the available hospitals and emergency hospitals (such as the El Amin hospital in Haifa and the Borochov hospital in Ahuza). The destruction in Palestine seen by the members of the commission is described by them as "shocking and terrible."

By the beginning of January 1948, it had become clear that attacks on physicians, nurses and Red Shield ambulances were considered normal by the Arab fighters. On January 6 an appeal was made by the Jewish Medical Association and the Arab Medical Association, for respect of the immunity of physicians, nurses and hospital staff, irrespective of race, origin and creed. This appeal was not heeded. Attacks on Jewish medical personnel, ambulances and hospitals continued unabated, in spite of the endeavors made by the Arab and Jewish medical organizations. The Arabs did not hesitate to attack funerals, and they were abiding by no convention concerning Jewish wounded persons and prisoners. On March 31 the Jewish Agency and the Arab Higher Executive assured the International Red Cross Society that they would welcome a Red Cross delegation to Palestine which would care for the victims of the present disturbances. Dr. de Reynier said that activities of the International Red Cross would commence immediately on the written agreement of both parties to the Geneva Convention. A Red Cross commission, consisting of eight commissioners, four physicians and ten nurses, has been planned. The Red Cross intends not to open hospitals of its own but to attempt to keep existing hospitals, as well as first aid stations, ambulances and the members of the medical profession immune from attacks. The Red Cross will, furthermore, care for the wounded, the evacuation of women and children from the battle zones and the setting up of neutral areas for limited periods, where persons could find refuge from the fighting. Some of these intentions have already materialized in the Jerusalem area, inasmuch as the entire complex of the Government Hospital in Jerusalem has been placed under the supervision of the Red Cross and under the administration of the Arab Medical Association. Negotiations have also taken place regarding the establishment of so-called "Geneva Islands" (neutral places as previously described). The budget for the administrative work of the International Red Cross in Palestine has been fixed at 1,000,000 Swiss francs, contributed jointly by the Palestine government, the Jewish Agency and the Arab Higher Executive.

All these endeavors did not prevent the catastrophe of April 13, when Arab bands attacked the staff of the Hadassah Hospital and members of the Hebrew University, who were on their way through the Sheikh Jarrah Quarter of Jerusalem to the Hadassah and University premises on Mount Scopus. Seventy-six Jews were murdered in this attack and 21 wounded. There were ten vehicles in all in this Hadassah convoy, three containing solely physicians, nurses and patients. Some of the vehicles were clearly marked with the insignia of the Red Shield. Among the dead were the Director of the Hadassah Hospital, Dr. Chaim Yassky; Dr. Doljanski, the head of the Department of Experimental Pathology and of the Cancer Research Laboratory; Dr. Ben David, Secretary to the Committee of the Medical Faculty, and Dr. B. Miszurski, assistant to Dr. Doljanski. The tragedy of this massacre is best described in the words of the few survivors, Dr. I. M. Bromberg and Dr. Ullman:

> About 9:45 a. m. the ambulance in which we were traveling hit a mine and fell into a road trap, and the engine was damaged. The ambulance was a few meters behind the escort car and a few meters in front of two buses which were also damaged. The vehicles were peppered with bullets, and at 10:15 a. m. the first bullets penetrated the ambulance. Dr. Yassky was the first person to be wounded, some pieces of shrapnel hitting his leg. Many hundreds of shots were fired at the vehicles, some from heavy weapons, and explosions occurred nearby.
>
> Those in the ambulance were the drivers, Dr. and Mrs. Yassky, one wounded patient on a stretcher, the assistant matron of the hospital and six other physicians.
>
> Dr. Yassky sat next to the driver throughout and opened the peephole of the ambulance from time to time to see what was going on and to report on events. His movements were quickly observed by the Arabs, and it became clear that he had become a special target, because the largest concentration of bullets was directed at his part of the vehicle. It was suggested that he move farther back into the ambulance, but he refused, wishing to stay at his observation post and to encourage the driver.
>
> At 11:15 a. m. the second casualty occurred in the ambulance, when Dr. Matoth, children's physician, was also hit by shrapnel. At 12 noon Dr. Yassky reported that Arabs were coming much nearer and that large numbers were massing for what appeared to be the kill. At 1 p. m. Dr. Yassky said "This looks like the end. We must say goodbye."
>
> A little later, a convoy of British Army cars was seen by Dr. Yassky to turn into the Ramallah Road. He shouted to them for help and waved

a white handkerchief, which he reported must have been clearly seen by the soldiers.

At 2 p. m. a second army convoy took the same road, and again they were signalled. There was no help forthcoming.

At 2:45 p. m. more bullets penetrated the car near Dr. Yassky, and he was slightly wounded in the face. A little later he reported that one of the buses was burning and that its occupants must be dead. Soon afterward he reported that the second bus was burning. He then said farewell to the occupants of the ambulance and to his wife, and the other passengers also began to say farewell.

Just after 3 p. m. a bullet penetrated the lower part of the ambulance, apparently passing through the engine, and hit Dr. Yassky in the region of the liver. He began to bleed profusely. He asked for an injection of morphine, which he was given. He said a final word to his wife and his staff and to the patient on his stretcher.

The passage of time in the ambulance became blurred. One or two persons actually dozed off at intervals, and all were resigned to their death. Many made neat packages of their watches and personal belongings, which they stowed away in the ambulance, and sat awaiting their bullet. Indeed, several were impatient for this bullet to come, because on several occasions waves of Arabs had approached to within a few meters of the cars, out to slaughter.

Around noon, the driver of the vehicle, Zecharia, thought that it was better to run for it than to sit and await butchery in the ambulance. He was killed a few moments later. Later, one of the physicians also thought that the slim chance of a run for safety was better than the certainty of being killed in a trap. Though wounded, he got out of the car, and his run for safety was a crawl on all fours to Antonius House, which he reached, to be saved by the small British unit in occupation of this building, about 20 yards from the ambulance.

At 3 p. m. two army ambulances passed by the stranded cars; help was asked for and again was not given.

Some time during the afternoon, a number of "Molotov bottles" hit the ambulance, but failed to set it on fire. One of the wounded bus drivers crawled to our ambulance and was able to get into the driver's seat. He became impatient, decided the occupants of the ambulance had no chance, crawled out again and was killed.

All these macabre happenings took place against a background of bullets, bombs, mortars, "Molotov bottles" and hordes of Arabs crazed with an orgy of shooting.

The ordeal lasted seven hours, and then, at 4:30 p. m., British help arrived. Since this help was extended, all occupants of the ambulance have been unanimous in declaring how helpful and considerate the manner was.

New Blood Pressure Principle of Anterior Lobe of Hypophysis

Proceeding from the observation that after hypophysectomy of rats the blood pressure sinks as it does after adrenalectomy, H. Hase (Tel-Aviv) attempted experimentally to find the principle responsible in the hypophysis for the maintenance of the blood pressure. The hypophysis extract used for this purpose was dialyzed after acid hydrolysis, and the last dialysate was used for the experiments. The tests were made with rats; the nonbloody method of Byron and Wilson was used to determine the blood pressure of the rat tail. As hypophysectomized rats could not be obtained for the experiments, the animals were made hypotonic through the elimination of the adrenals. The normal blood pressure value of the test animals was between 130 and 140 mm. After the elimination of the adrenals, values between 85 and 90 mm. could be measured. After injection of the hypophysis extract, the blood pressure increased, reaching a peak after one and a half to two hours and returning to its starting point within the next twenty-four hours. In two publications (*Nature*, Dec. 6, 1947, and *Acta Medica Orientalia*, Jan.-Feb. 1948) Hase pointed out the significance of this new blood pressure factor. He expressed the belief that this principle was particularly important in the treatment of blood pressure disorders caused by hormonal disturbances. Clinical examinations of persons suffering from hypotonia and presenting, at the same time, endocrine disturbances, showed reactions to the injected extract of the anterior lobe of the hypophysis with a temporary increase in the blood pressure and partial improvement of the disturbed endocrine functions (testes or ovaries). The extract used was clearly free of gonadotrope substances.

The death of Hase, in February 1948, interrupted these studies which were carried out in the laboratories of the Teva Middle East Pharmaceutical and Chemical Works Ltd., Jerusalem.

A New Outbreak of Typhoid in Palestine

In the beginning of May, a new outbreak of typhoid fever was reported from the Arab town of Acre. There is no doubt of the epidemic character of this outbreak, and the disease has already spread to neighboring villages, particularly to Satr Amr. The source of infection seems to be the municipal drinking water. The spreading of the disease has been favored by the large influx of Arabs from Haifa, since the necessary control measures can hardly be carried out during the present disorders. British military and police personnel have also been infected, and the latest known figures of persons implicated are as follows: 54 British soldiers, 10 British police and 70 civilians. The difficulties encountered in fighting the epidemic in the present circumstances are shown by a report stating that in Acre Arabs killed an army sergeant and wounded 2 soldiers who had brought dichlorodiphenyltrichloroethane (DDT) for use in the town.

Importance of Complement Fixation Test for Amebiasis

In a paper read before the Palestine Jewish Medical Association, Tel-Aviv Branch, H. Steinitz reported on 70 cases of various abdominal troubles. All the patients were examined thoroughly, many during long periods in hospitals. An exact diagnosis was not made, but the patients showed positive reactions to the complement fixation test for amebiasis (performed by A. Klopstock with his modification of Craig's method). Included in this series were some cases of acute amebic hepatitis, besides a number of cases of subacute and chronic hepatitis and chronic intestinal amebiasis (without amebas in the feces). The antiamebic treatment, performed on the basis of the positive reaction to the serologic test, proved highly successful in about 75 per cent of the cases (including all the acute cases), a therapeutic result considered as satisfactory, since results have not been better in cases in which there were positive observations of Amoeba histolytica in the feces.

In the opinion of H. Steinitz the complement fixation test is indicated in all cases of abdominal disturbances, acute as well as chronic, with unclear diagnosis, and particularly in those cases in which, in spite of many examinations, a definite diagnosis has been impossible. The complement fixation test should also be made when no improvement has resulted from antiamebic therapy. A further indication is the impossibility of examination of the feces on the spot, owing to the lack of experienced examiners or the necessity of sending specimens for examination over long distances, e. g., in rural districts. A positive result in a complement fixation test in undiagnosed abdominal diseases is helpful in the diagnosis "amebiasis" and allows the physician to undertake antiamebic therapy.

In the discussion which followed, Sandler reported on his own experiences with the complement fixation test with patients of the Workers' Sick Fund. He came to conclusions similar to those of Steinitz. Klopstock gave a short report of the examination of about four thousand specimens (to be published shortly *in extenso*), pointing out the important significance of a positive reaction to a complement fixation test. The reaction is specific for amebiasis, but further technical improvement will be necessary to improve the results. Most of the other participants in the discussion acknowledged the importance of these investigations and pointed out the necessity of further extensive examinations to clarify the possibility of a more exact diagnosis of the amebic infection—a problem of particular importance for Palestine, with its high rate of infection with amebiasis.

AUSTRALIA

Pharmaceutic Benefits Crisis

A situation without parallel in medical history exists in Australia today. An enactment by the commonwealth government has been nullified by the combined action of the medical profession.

From June 1 every Australian was entitled to have a limited range of medical prescriptions dispensed without payment to the pharmaceutic chemist. While the actual number of prescriptions so dispensed will not be known until the government checking staff has received the chemists' claims at the end of the month, available evidence suggests that the total is negligible. Far from being annoyed at the refusal of the doctors to take part in the scheme, the Australian public is apathetic and adopts the attitude of a detached spectator of a battle of tactics. There is a growing public aversion to socialization in Australia. Two days before the plan was brought into force, the people, through a referendum, gave an emphatic negative to the government's referendum on price fixing.

The government's scheme is that prescriptions will be limited to a formulary and must be written on a prescribed form. The British Medical Association voices the attitude of all doctors in Australia when they make three objections to the "free" medicine plan:

1. The limitation of prescribing to a restricted formulary interferes with a doctor's duty to prescribe according to his professional judgment. Estimates indicate that the formulary would cover only about half the prescriptions normally written. The formulary is not as wide as the British Pharmacopoeia and (to the horror of manufacturing chemists) does not include proprietary preparations.

2. Although the minister for health (Senator McKenna) promised that there would be no penalty clauses against doctors, the medical practitioner finds himself beset with instructions, failure to comply with which leave him liable to a penalty of 50 pounds ($150). One of these instructions is that the doctor will not use a government prescription form for any other purpose than the writing of a prescription "in accordance with, and for the purpose of the Act and these Regulations. Penalty: Fifty pounds."

3. None of the recommendations by the British Medical Association (at the request of the government) for extension of the formulary were included.

Less definite but equally cogent objections to the scheme are:

1. It is the beginning of a national medical service by back-door methods.

2. It is both difficult and dangerous to make a patient's disease fit a formulary.

3. The scheme placed in the hands of the director-general of health the complete control of medical prescribing. It was an example of government by regulation.

In a bitter attack on doctors in the national parliament June 15, the minister for health drew attention to the "social and professional ostracism exercised by doctors against doctors. It is one of the cruelest, most vicious, unchristian things within the law in this country." He criticized doctors who earned great wealth from the sick and suffering of the community, yet denied financial relief to their patients. The doctors' objections to the penalty clauses, said the minister, were not only without merit, but were utterly fantastic.

The spokesman for the British Medical Association, Dr. J. G. Hunter, general-secretary of the federal council, replied to this outburst by pointing out that their boycott policy was determined by the rank and file of the profession and that the British Medical Association merely acted as a mouthpiece. The minister's statement on the scheme was described as "characterized by distortions and omissions." The minister's claim that 95 per cent of chemists' prescriptions came within the formulary was completely and absolutely untrue. Abuse of the British Medical Association was no argument in favor of "free" medicine.

The British Medical Association has offered to participate in the plan if: (1) penalty clauses are deleted, and control of doctors maintained by a professional committee from their own association; (2) doctors use their own prescription forms; (3) any doctor's prescription will be dispensed by the chemist without charge to the patient.

The present attitude of the British Medical Association is that no further negotiations will be entered into with the minister for health unless he expresses his willingness to make, as a basis of negotiation, elimination of (*a*) government prescription forms, (*b*) all penal clauses applicable to doctors and (*c*) limitation of prescribing to a formulary.

June 21, the federal president of the British Medical Association (Sir Henry Newland) announced that he had received a letter from the minister, inviting the British Medical Association to a conference on these points.

The government, meanwhile, has placed itself in a difficult position by anticipating the implementation of the plan and collecting a social services contribution from taxpayers for the financial year 1946-1947. Public pressure is thus brought on the government to settle its dispute with the doctors.

Artificial Insemination

Referring to the report on this subject in The Journal, May 8, page 170, obstetric hospitals in Australia are beginning to adopt the principle of artificial insemination, but the procedure is not often successful.

The first of 7 babies resulting from artificial insemination was recently born in Sydney. In Brisbane 6 women have been inseminated without result. In most of these cases, the husband has been the donor. It is believed, however, that some babies have been born in Australia as a result of insemination by donors other than the husband.

Owing to the absence of legal protection for all concerned, information of such procedure is difficult to obtain. Theologians are outspoken in their condemnation, the Roman Catholic church particularly. Recently, the Church of England in Australia, through Bishop Dixon stated:

"The faithful should declare exactly where it stood if they were to accept attacks on the sanctity of marriage, or if there was failure to check suggestions of the use of artificial means for bringing about human birth. The latter would result in cruelty to individuals brought into existence knowing nothing of their parentage, or the grave dangers by which they must be handicapped from birth."

BELGIUM

(From Our Regular Correspondent)

Liége, June 22, 1948.

Doctors Fighting Against the Government

A most acute controversy has arisen between the Belgian Medical Federation and the Secretary of the Treasury (Minister of Finances). The creation of a fiscal notebook for all the fees collected by the physician, in which the nature of the fee should be indicated for those who are subjects of insurance against diseases, has caused a general revolt of the medical profession. In fact, the fiscal inquiry makes medical secrecy, which is the basis of professional ethics, meaningless to a larger extent than it is realized. The great Belgian medical association, *Fédération Médicale Belge*, has realized an impressive referendum: 6,000 of 8,000 practitioners have declared themselves ready to support the claims and to refuse the use of the fiscal notebook. By an important majority the representatives of the general assembly have decided that in case penalties should be imposed on the physicians, the Belgian Medical Federation immediately will go on administrative strike.

This administrative strike will consist of not filling out any administrative papers except: (*a*) medical prescriptions on personal stationery; (*b*) testimony ordered by articles 55 to 57 of the Civil Law and article 361 of the Criminal Law compelling the physician to report a birth in the absence of the father, and (*c*) reports of contagious diseases (royal ordinance of June 10, 1922).

If physicians should be imprisoned, the Belgian Medical Federation will not hesitate to declare a strike, withholding medical attendance except for emergency cases.

This unanimity of the members of the medical profession and this firmness provide a good outlook in the fight against the progress of state management of medicine. In fact, if the medical profession continues this united resistance, it will have the experience—and this will be a convincing one—of the immense advantage which the abolition of payments by a third party would involve for the profession. In the present circumstances the doctor gets his fee from the patient and ignores the entire organization of insurance against disease or mutual insurance which should pay in his stead. It is a return to the total emancipation of medicine, a situation which should never have been abandoned if medicine was to remain a free and justly honored profession.

STATISTICAL ANALYSIS OF "TREATMENT OF MENINGITIS WITH SULFADIAZINE AND SULFAMERAZINE"

To the Editor:—In the January 3 issue of THE JOURNAL, page 8, appeared an article by Zeller, Hirsh, Sweet and Dowling entitled "Treatment of Meningitis with Sulfadiazine and Sulfamerazine," in which the results of therapy with a combination of sulfadiazine and sulfamerazine in 75 cases of meningococcic meningitis are compared statistically with the results achieved against this disease in previous studies using either sulfadiazine or sulfamerazine alone. Unfortunately, the authors arrive at conclusions which are not supported by their own results but are based on the fallacious interpretation of statistical data.

Dr. Dowling began therapy with the sulfadiazine-sulfamerazine combination following my suggestion at the occasion of his personal visit to my laboratory in the fall of 1944. However, he and his co-workers arbitrarily increased the dosage of the combination "25 to 33 per cent" above the generally accepted routine dosage of sulfonamide drugs. Thus, adult patients received 8 to 9 Gm. of the combination daily as contrasted to the 6 Gm. maintenance dose used by these authors previously with either sulfadiazine or sulfamerazine. Consequently, each patient on combination therapy received an additional amount of at least 21 Gm. of a sulfonamide drug in the average ten day treatment period! While the authors neither claim nor prove the necessity for such a substantial increase in dosage when using the sulfadiazine-sulfamerazine combination, they formulate their conclusions on the advantages and disadvantages of mixture therapy as if they had used the ordinarily required dosage and thus present an entirely misleading picture. The chief advantage of sulfonamide combinations—the avoidance of renal complications—is obscured, and the possible increase in sensitization reactions is given undue prominence. Moreover, "in most patients in the present series, the initial dose (8 Gm.!) and one or two subsequent dosages were given intravenously" (p. 8), so that each patient received 14 Gm. of sulfonamide combination intravenously in the first twenty-four hours. When using the smaller dosage of single sulfonamide drugs, Dowling and associates employed the oral route as a rule, reserving intravenous therapy for the severely ill and stuporous patient (Sweet, L. K.; Dumoff, S. E., and Dowling, H. F.: Meningococcic Meningitis Treated with Sulfadiazine and Sulfamerazine: A Three Year Study, *Ann. Int. Med.* **23**:338, 1945). It is common knowledge that administration by vein increases the danger of renal complications sometimes as much as 50 per cent (Plummer, N., and Wheeler, C.: The Toxicity of Sulfadiazine: Observations on 1,357 Cases, *Am. J. M. Sc.* **207**:175 [Feb.] 1944). Statistical comparison is further complicated by the use of serum therapy with single sulfonamide agents and the elimination of this measure in the present series and also by the great variations in mortality figures (20 to 90 per cent) in different epidemics of meningococcic meningitis (Lepper, M. H.; Sweet, L. K., and Dowling, H. F.: The Treatment of Meningococcic Infections with Sulfadiazine and Sulfamerazine, *J. A. M. A.* **123**:134 [Sept. 18] 1943). Hence, it seems hardly possible to obtain valid data on comparative case fatality rates in evaluating small series of patients unless alternate patients are treated with single and combined sulfonamide agents in the same epidemic, a measure employed by the authors when comparing sulfadiazine and sulfamerazine (*Ann. Int. Med.* **23**:338, 1945). The two reasons put forward by Zeller and co-workers in their explanation of the use of this excessive dosage schedule (p. 11) are unsound and highly objectionable. To my knowledge no better clinical results were predicted by proponents of the sulfonamide mixture therapy. Rather it was contended that the relative increase in solubility would permit the use of higher dosages wherever necessary without a prohibitive increase in the incidence of renal complications. This contention was fully confirmed in the study under discussion. In our own experience, now based on the treatment of more than 1,000 patients with various acute infections including meningitis, sulfonamide combinations produced highly satisfactory clinical results at the routine dosage level without any renal complications (Lehr, D.: Prevention of Renal Damage by Use of Mixtures of Sulphonamides: Animal-Experimental and Clinical Studies, *Brit. M. J.* **2**:943 [Dec. 13] 1947). Moreover, it is impossible to follow the reasoning of Zeller and co-workers, that the claim of better clinical results with sulfonamide mixtures could be investigated by the employment of higher dosages. Logically, the prerequisite of such proof would hinge on the use of equal amounts of sulfonamide drugs in the series slated for comparison. Otherwise, what evidence can the authors provide that the combination would not have rendered identical therapeutic results at the 6 Gm. daily dose, obviously with a further significant decrease in the incidence of renal complications? This assumption is supported by the conclusion which Dowling and co-workers derive from a three year study on the "Treatment of Meningococcic Meningitis with Sulfadiazine and Sulfamerazine," namely, that high sulfonamide concentrations in the blood bore no direct relation to recovery in patients with meningococcic meningitis. The authors must have been aware also that raising the dosage in a mixture of only two sulfonamide drugs meant the removal of much of the basic advantage on which the principle of combination therapy rests. H. F. Dowling and M. H. Lepper (Toxic Reactions Following Therapy with Sulfapyridine, Sulfathiazole and Sulfadiazine, *J. A. M. A.* **121**:1190 [Apr. 10] 1943), among others, reported that the frequency of renal calculi varied in direct proportion to the maximum level of the sulfonamide compounds in the patient's blood. They found that calculi occurred only when dosages larger than 3 Gm. of sulfadiazine or sulfathiazole were given in twenty-four hours. Dowling and co-workers (Relative Toxicity of Sulfadiazine and Sulfamerazine, *J. A. M. A.* **125**:103 [May 3] 1944) also reported that sulfamerazine causes significantly more kidney damage than sulfadiazine. It follows that the upper limits for the safe use of a sulfadiazine-sulfamerazine combination without alkalization lies in the 6 Gm. routine dosage or below this amount. Consequently, the authors' statement that the second reason for the use of a higher dosage was "to explore the upper limits of dosage at which the mixture could be safely administered" is strange indeed.

Despite the fact that the sulfadiazine-sulfamerazine combination was put at such obvious disadvantages in the comparison with the separate compounds, the results reported, except for an apparent increase in allergic reactions, are all in favor of the combination. There was a lower case fatality rate in all age groups receiving the sulfadiazine-sulfamerazine combination, as well as in patients grouped in accordance with the poorest prognosis. There were much fewer "complications related to disease," 14 per cent for the mixture as compared to 26 per cent for the single drugs. (This difference, incidentally, approaches statistical significance when tested by the chi square method.) There was finally a substantially lower incidence of renal complications as well as a lowered incidence of nausea, vomiting, leukopenia and anemia, despite the fact that patients on combination therapy had the highest blood levels and received a 25 to 33 per cent higher dosage than patients treated with either sulfadiazine or sulfamerazine alone.

With regard to allergic reactions, one is struck by the unusual combined tabulation heading, "Fever and/or Rash and/or Conjunctivitis," which seems to attach undue significance to conjunctivitis alone as a sensitization reaction. The combined reporting of these three reactions makes it impossible to elucidate the exact position of conjunctivitis in the over-all picture of reactions counted as allergic in nature. However, it seems fair to assume that the exceptionally high figures for sensitization reactions reported by Dowling and co-workers for the separate compounds as well as the combination, which are in conspicuous contrast to most reports in the literature, are due to the inclusion of conjunctivitis alone as an allergic reaction. Although conjunctivitis is seen occasionally accompanying other sensitization reactions from sulfathiazole, it seems extremely rare from sulfadiazine and its homologues. Plummer and Wheeler reported 1 case of conjunctivitis among 1,357 patients receiving full sulfadiazine therapy without qualifying the nature of this reaction. Most authors reporting toxic reactions from sulfadiazine or sulfamerazine do not mention the occurrence of conjunctivitis. Dowling himself (Dowling, H. F.; Hartman, C. R.; Sugar, S. J., and Feldman, H. A.: The Treatment of Pneumococcic Pneumonia with Sulfadiazine, *J. A. M. A.* **117:** 824 [Sept. 6] 1941) saw no conjunctivitis in 137 patients with pneumococcic pneumonia treated with sulfadiazine. Hence, the frequency of this reaction in meningitis would speak for connection with the infection. Associates and I have not observed any instance of conjunctivitis alone as an allergic reaction in our large series treated with the combinations sulfathiazole-sulfadiazine and sulfadiazine-sulfamerazine. Moreover, in our experience the incidence of drug fever and rash remained at the same low level as indicated in previous reports (Lehr, D.; Slobody, L. B., and Greenberg, W. B.: The Use of a Sulfadiazine-Sulfathiazole Mixture in the Treatment of Children, *J. Pediat.* **29:**275 [Sept.] 1946). A full explanation of this observation is beyond the scope of this discussion; it will be published elsewhere. Briefly, however, it should be stressed that the widely accepted belief that the production of sulfonamide allergy is independent of the size of the dosage has no basis in fact. On the contrary, there exists overwhelming evidence that within limits the incidence of sensitization is directly proportional to the tissue concentration of each sulfonamide compound. Hence, if one refrains from the use of excessive amounts, combinations of two or more sulfonamide drugs in partial dosage may result in an actual decrease of the incidence of allergic reactions despite the simultaneous presence of several independent allergens. This contention could serve to explain the low incidence of drug fever and rash observed in our series, even after prolonged therapy. Our own findings and the objection raised against the inclusion of conjunctivitis alone as an allergic reaction make it appear doubtful whether any significance can be attached to the increase in sensitization reactions reported by Zeller and co-workers in their small series.

Finally, in the statistical evaluation of the results, the authors have made liberal use of the chi square method. Readers unfamiliar with statistics are likely to draw wrong conclusions from the fact that none of the authors' measurements revealed statistically significant differences between sulfadiazine and sulfamerazine used as combination (group A), and separately (group B). For example, the fatality rate observed in group A was 6.7 per cent and in group B was 10.1 per cent. In the present instance this difference is "statistically not significant," meaning that a definite conclusion cannot be reached that method A is better than method B, because this percentage difference is based on such a small sample. The difference might be due to chance alone. However, it does not mean that method B is as good as method A. If these same percentages had been found in sample groups of 600 each, the difference would be statistically significant. Since every one of the authors' measurements was "statistically not significant," which is another way to saying that the evaluation with such small samples was inconclusive, the statistical data do not permit any conclusions as to the advantages of one method over the other. Hence, the authors have wrongly interpreted the chi square tests to mean that there is no difference between method A and method B, as regards fatality rate and the incidence of renal complication, while the results of these tests merely suggest the necessity for collection of more data.

In summary, then, the authors have failed to provide any valid evidence that with the doses required for the treatment of meningococcic meningitis the disadvantages of using a mixture of sulfadiazine and sulfamerazine outweigh the advantages.

David Lehr, M.D., New York.

TRANSIENT CEREBRAL PARALYSIS

To the Editor:—In a recent report in The Journal entitled "Transient Cerebral Paralysis in Hypertension and in Cerebral Embolism" (J. A. M. A. **137:**423 [May 29] 1948), Pickering challenged the hypothesis that cerebral angiospasm is responsible for hypertensive encephalopathy, pointing out that cerebral vessels have relatively thin walls and that they react poorly to vasoconstrictor agents. This author furthermore expressed the view that sudden organic arterial obstruction, for example by a thrombus, and not vasospasm is the cause of the transient paralyses observed in hypertensive disease. This concept is based on his observation that embolic occlusion of cerebral arteries produces attacks that are "precisely similar in kind and range to those occurring in hypertension." Thus in either condition, according to this author, paralyses may be transient or permanent depending entirely on the establishment of a collateral circulation.

What Pickering failed to consider, however, is that the similarity between the attacks associated with cerebral embolism and those with hypertensive encephalopathy might well be the result of a common denominator other than organic arterial obstruction; namely, cerebral angiospasm itself. That arterial embolism is commonly associated with intense vasospasm of the adjacent vascular channels has been established. It has also been recognized that vasoconstriction arising in this manner is often a more potent cause of the ischemia than the organic occlusion itself. The development of such vasospasm, therefore, and its subsequent disappearance in cases of cerebral embolism might well explain the transient character of the episodes observed in some instances.

It would indeed be impossible to explain the recurrence of identical seizures in a hypertensive patient ten, twenty or more times in a day or in the course of a year or more on the basis of organic arterial occlusions.

Although cerebral arteries allegedly possess feeble contractility, Pickering is unable to explain Penfield's observation of intense vasoconstriction of the arteries of the exposed cortex following an epileptic attack induced by electrical stimulation (Penfield, W.: The Circulation of Epileptic Brain, *A. Research Nerv. & Mental Dis., Proc.* **18:**605, 1938).

Our own studies in which papaverine in large oral dosage successfully prevented the attacks of hypertensive encephalopathy (J. A. M. A. **136:**930 [April 3] 1948) and idiopathic epilepsy (to be published) add further evidence in support of cerebral angiospasm as the underlying basis for these conditions.

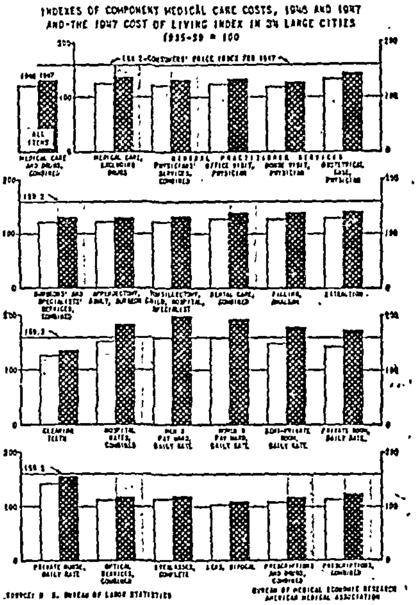
Medical Economics

COMPARATIVE INCREASES IN THE COSTS OF MEDICAL CARE AND IN THE COST OF LIVING

FRANK G. DICKINSON, Ph.D.
Director, Bureau of Medical Economic Research
Chicago

Frequently physicians ask if the general cost of living has risen faster or slower than a fee or service rate charged by physicians. A rather satisfactory answer is provided for the thirty-four large cities in which field representatives of the U.S. Bureau of Labor Statistics gather sample data monthly or quarterly. Their compilations for 1947 have been made available.

Except for hospital items, the index of the cost of living (now called "consumers' price index for moderate-income families") for 1947 was higher *than the index of any reported medical care item.*[1]



SOURCE: U. S. BUREAU OF LABOR STATISTICS

BUREAU OF MEDICAL ECONOMIC RESEARCH AMERICAN MEDICAL ASSOCIATION

The chart shows the indexes for 1946 and 1947. The sharp rise in hospital rates is noteworthy. In each section of the chart the consumers' price index for 1947, 159.2, is shown as a horizontal line. It should be noted that the index for "medical care and drugs combined" for 1947 is 131.6 and for medical care excluding drugs, 135.3. For physicians' services (general practitioner) combined the index for 1947 stands at 130.3.

House visits at 125.3 are not as high as office visits, 132.4. Obstetric cases show the highest index, 143.7, in this group for 1947.

Hospitals have been exposed to the full impact of inflation during the forties. Consequently, the index for hospital rates combined in 1947 is 179.6, a sharp increase from 1946, when the index was only 150.6. Observing the several hospital indexes separately, the highest in 1947, 194.4, is for men's pay ward daily rate. The lowest of these indexes for 1947 is 108.2 for the bifocal lens.

A number of indexes of drug items such as acetylsalicylic acid and quinine are not included. Data regarding these items can be found in "*Indexes of Retail Prices of Services and Miscellaneous Goods*",[2] pages 10-1 to 10-3.

These consumer price indexes date back to 1935; the 1935-1939 average has been set equal to 100. In the table appears the yearly index number starting with 1940 for each of the medical care items exclusive of the particular drug items already noted. The table has been so arranged that the summary item appears first and the component items in the line or lines immediately below.

Although the behavior of medical care prices in thirty-four large cities does not reflect the price changes in all towns and cities where physicians practice, it does provide a rather clear picture of the general trend of prices American people are paying for their medical care. The inescapable conclusion is that the cost of these important items of medical care has risen since 1940 but, *with the exception of hospital items, not as* rapidly as the general cost of living. This conclusion reinforces and substantiates the conclusions in my study of the costs of medical care.[3]

In this earlier study the conclusions were that medical care items as a whole cost the American people $5,600,000,000 in 1946 but that only 3.9 per cent of total personal consumer expenditures of the American people were spent for these medical care items; this compared with 4.3 per cent in 1940. More particularly, in 1946 the amounts spent for physicians' services and hospitals were 1 and 0.6 per cent of total personal consumer expenditures in that year. Hence, the general conclusion was that the American people were spending a smaller percentage of the total consumer budget for medical care as a whole and for physicians and hospitals as components thereof.

In 1946 physicians received only 26 per cent of all the dollars spent for medical care as compared with 31 per cent in the base period, 1935-1939, and 32 per cent in 1929, the first year for which the data were gathered and published by the U.S. Department of Commerce.

The amount spent for drugs in 1946 had risen to 24 per cent of all dollars spent for medical care as compared with only 21 per cent in the base period, 1935-1939, and 20 per cent in 1929. Thus the story of the wonder drugs is written into the recent history of medical economics. The percentages for hospitals were 16, 17 and 13, respectively; for dentists the percentages were 13, 13 and 16. It was also stated in my earlier study that the people are getting more for their money. They get well quicker, they live and earn longer. The type of medical care given in 1946 differs as much from the type given in 1929 as a 1946 passenger automobile differs from a 1929 model.

Whether one examines the record of total expenditures of the American people for medical care or the prices of significant items during recent years, the general conclusion is warranted that the American people have been fortunate in that the costs of keeping well have not risen as rapidly as the cost of living.

---

[1] *The consumers' price index covers seven groups of items.* (Monthly Labor Review 66:235 [Feb.] 1948). The seventh group, Miscellaneous, covers many items including the medical care items.

This article is a condensation of a report recently published by the Bureau of Medical Economic Research. A copy will be sent on request to association headquarters.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Constitutionality of Law Repealing Naturopathic Practice Act.—This was a suit by a number of naturopaths against the attorney general to determine the validity of chapter 2 of the Public Acts of 1947, which chapter repealed the existing naturopathic practice act and prohibited the practice of naturopathy in the state. The trial court upheld the validity of section 1 of the act (repealing the existing naturopathic practice act) but struck down section 2 (prohibiting the practice of naturopathy in the state) on the ground that it constituted an unwarranted abuse of the police power of the legislature. The effect of this decree was to remove from the Tennessee code the provisions as to licensing of applicants to practice naturopathy but to leave in effect the licenses granted from 1943 to 1947. There are some two hundred licensed naturopaths in the state. From this decision the attorney general appealed to the Supreme Court of Tennessee.

In construing a statute, said the Supreme Court, it is permissible to take notice of the conditions existing at the time of its enactment. At the session of the general assembly previous to the one enacting this statute, a committee was appointed to investigate the unlawful practice of the healing arts. The committee's report revealed that licenses to practice naturopathy had been issued to wholly unqualified persons; that they had been purchased; that they had been issued as a result of fraudulent cooperation; that a number of corporations had been chartered by naturopaths to issue certificates of compliance with the educational requirements of existing statutes, and that some of these chartered schools issued diplomas to persons who had attended the schools for a period of time not in excess of one week, but which diplomas certified that the holders thereof were qualified in a number of subjects dealing with the arts. The enactment of chapter 2, Public Acts of 1947 followed.

As we conceive the legislature intent, the Supreme Court continued, as gathered from the face of the Statute and from existing conditions, it is that the prohibitions of the statute were directed at persons engaged in the practice of naturopathy and were evidenced, first by a bar to all future licensing of such and, second, by a restriction against the use of the licenses theretofore issued. In enacting the statute the legislature intended to prevent the practice of naturopathy by persons who have only limited qualifications and do not possess what might be termed a general practitioner's or osteopath's certificate; it did not intend to prohibit the performance of the acts which the naturopathic licensing act included within the definition of the practice of naturopathy. Physicians are licensed under chapter 181 of the Public Acts of 1945, and osteopaths under section 7003 et seq of Williams' Code. These generally licensed practitioners are not prohibited from performing the acts in question. The effect of the statutes governing the practice of medicine, the practice of osteopathy and the present statute is that no person shall practice naturopathy unless he be licensed either as a general practitioner or as an osteopath. It cannot be disputed, said the Court, that the legislature has the right to require a general practitioner's license for those who desire to practice a limited branch of the healing arts, and the present statute therefore may be treated as one imposing additional qualifications on persons already in the practice of the profession. It discloses an effort on the part of the legislature to regulate one phase of the healing arts and should be construed in pari materia with other statutes on this subject.

Dr. Herzog in his work on Medical Jurisprudence very clearly calls attention to the dangers flowing from the limited knowledge of the limited practitioner as follows:

> While electro-therapy, mechano-therapy, hydrotherapy, suggestive therapeutics, and certain other forms of treatment for which licenses are issued to limited practitioners are valuable in many pathological conditions, the limited practitioner is likely to do a great deal of harm, not only because he is not thoroughly educated as a physician but, as he is only licensed to use a certain system of treatment, he is apt to use it in cases to which it is not adapted.

Obviously a much more accurate diagnosis may be expected from a general practitioner who has studied medicine and disease in all its phases than from a limited practitioner with only limited preparation therefor, and an accurate diagnosis of an ailment lies at the very foundation of successful methods of treatment. After all, concluded the court, why should not persons who hold themselves out to be doctors, who not only rub and massage patients but prescribe medicine for them, even though narcotics and sulfonamide drugs are prohibited, be required to have the training of a medical doctor? Evidently the legislature thought there was too much borderlining in the practice of naturopathy and determined to stamp out the evil that was not in the science but in the practicing of it, to the definite injury of credulous sufferers.

Accordingly the Supreme Court held that the enactment of the statute in question prohibiting naturopathy in the state was a valid exercise of the police power of the legislature and that no unwarranted discrimination appears in the act. Petition for rehearing was denied and judgment of the trial court in favor of the plaintiffs was reversed.—*Davis v. Beeler, Attorney General, 207 S. W. (2d) 343 (Tenn., 1948).*

Compensation of Physicians: Patient's Obligation to Pay Reasonable Charge for Services.—The claimant, a dully licensed physician, presented to the estate of Ada J. McKeehan, deceased, a bill for professional services rendered the deceased prior to her death. The claim was contested by the residuary legatee and allowed, but in a smaller amount. The physician, therefore, appealed to the Supreme Court of Pennsylvania.

The claimant, a specialist in internal medicine, had been the deceased's physician for some sixteen years preceding her death and was the nephew of her deceased husband. During this period, he attended Mrs. McKeehan on many occasions at her home in Carlisle, at his office in Harrisburg and at the Harrisburg Hospital, where she had been a patient under his care four different times between 1939 and 1942. He made numerous physical examinations, blood counts and urinalyses for her and, on two occasions, took her to the University of Pennsylvania Hospital at Philadelphia and returned her to Carlisle. During these sixteen years Dr. Reckord never rendered any bill to Mrs. McKeehan and she at no time paid him for his services. His office records contained numerous entries showing visits by her to his office and by him to her home, as well as reference to services and treatments rendered by him, but no charges were entered. Following the death of Mrs. McKeehan, the claimant, at the instance of the executor of her estate, prepared and presented a bill for his services for the six years immediately preceding her death, in the amount of $9,410. An auditor, appointed by the court to pass upon the claim and make distribution, awarded the physician $5,000. This award was appealed to the Orphans' Court by both the physician and the residuary legatee, and a final decree entered in favor of the physician in the amount of $2,738. On appeal to the Supreme Court the residuary legatee contended that the evidence established that the claimant intended, when he rendered the medical services in question, that they were to be gratuitous and therefore the trial court erred in making any award to him whatsoever. The physician, on the other hand, contended that the services were not rendered gratuitously, that there always was an intention to charge for them, that the charges were reasonable and that the court erred in not awarding him the full amount of his claim.

It is well settled, said the Supreme Court, that "While there is an implied agreement to pay for the services of a physician if the services were intended to be and were accepted as a gift or act of benevolence, they cannot, at the election of the physician, create a legal obligation to pay." We agree with the trial court, however, that, under all the evidence presented in the instant case, it was a question of fact for the auditor to determine whether or not the claimant intended that his services, when rendered, were to be free of charge. There is sufficient evidence on which to predicate the finding of the auditor that the claimant did not so intend, but that he intended to charge although postponing the time of making an actual charge. This finding by the auditor, approved by the orphans' court, is entitled to the same weight as the verdict of a jury and cannot be disturbed, the Supreme Court concluded.

As to the matter of compensation for the services rendered, the Supreme Court continued, it is well established that "In the absence of an express agreement as to amount, the law implies a promise to pay for a physician's services as much as they are reasonably worth." Furthermore, "physicians should not have their services valued, as you would commodities in trade, by a fixed standard; what would be a proper charge for the same service to a man fully able to pay would be excessive to a man of limited means, and what would be willingly done for the indigent, without thought of financial reward, should be compensated for by one who can afford to pay on the scale which doctors of repute measure as the proper one." In order to substantiate the reasonableness of the amount of his claim, the claimant called two Harrisburg doctors, each of whom stated that in his opinion the services rendered by the claimant were worth $10,000. It must be borne in mind, said the court, that while the opinion of other physicians is competent on the question of the value of a doctor's services, it is not so conclusive as to take the place of the judgment of the court whose duty it is to pass on the question of the value of such services. In disregarding the testimony of the claimant's experts the trial court said that their opinions were based on all the evidence given at the first hearing before the auditor, some of which was incompetent. The opinions stated a lump sum for six years' services and no opinion was elicited as to reasonable charges for various types of service, such as office calls, laboratory work, examinations, home and hospital visits. The trial court also said: "We agree that the claimant visited and examined the decedent on many occasions. We cannot agree that each examination involved much time and skill in interpreting findings. The decedent apparently had a chronic condition and we gather from the evidence that the claimant's services were largely routine, checking pulse, blood pressure, heart, lungs, throat, making urinalyses and blood counts and from time to time prescribing medicines and drugs. We have made an exhaustive study and tabulation of all the records from which we are able to set out in detail the various services rendered by claimant. We have also determined from all the evidence what we deem to be the reasonable value of the services rendered, considering, inter alia, the type of service and the time consumed in rendering it and also considering, as admissions, the charges made to others." The Supreme Court therefore concluded that, under all the evidence, the trial court did not abuse its discretion in fixing the value of the claimant's services at $2,738. Accordingly the judgment of the trial court was affirmed. *In re McKeehan's Estate, 57 A. (2d) 907 (Pa., 1948).*

Hospitals, in General: Reasonableness of Fee as Question for Jury.—The plaintiff hospital sued to recover its fee for services rendered to the defendant following injuries sustained in a collision between a bus and a streetcar. From a judgment for the plaintiff, the defendant appealed to the Supreme Court of Oklahoma.

After the collision the defendant, while still unconscious, was taken to the plaintiff hospital at the direction of the street car motorman. She remained there and received treatment for two days. After she returned home she engaged a private physician and subsequently made two additional visits to the same hospital to receive treatment. In answer to the defendant's first contention, that she had never made any agreement whatever to pay for the services rendered, the court stated the general rule that the acceptance of valuable services and materials "raises a presumption of intent to pay, or that the services were to be compensated, or a presumption of legal liability, and while such presumption is not conclusive, it is sufficient to throw upon the person contesting liability the burden of showing an agreement or other circumstances indicating that the services were to be gratuitous." In the absence of any facts or circumstances indicating that the services were to be gratuitous, the court concluded, we hold that the defendant had no reason to assume or believe that the services rendered by plaintiff were gratuitous and that the evidence conclusively establishes an agreement implied by law that the defendant would pay the reasonable value of such services.

The defendant also contended however, that the value of the services rendered was a question which should have been submitted to the jury, regardless of the fact that the plaintiff's evidence of the value thereof was undisputed. The defendant denied the amount of the debt, and the only testimony on the subject was given by the physician who owned the hospital. He testified that "they are the usual, regular and reasonable charges for the services rendered." The court stated the general rule to be that the testimony of experts as to the value of professional services is not binding on the jury. Thus, in an action by a physician to recover compensation for professional services, the question of the value of the services is for the jury, even where the evidence of the plaintiff and his expert witnesses as to the value of the services is undisputed. The reason for this rule, said the court, is that while the testimony of an expert witness may not be arbitrarily rejected, it may be weighed by the jury in the light of their knowledge and experience, and if, when so weighed, it is found at variance with their knowledge or experience, they may accord it such weight as they deem proper in determining the value of services rendered. Such evidence, although standing alone, is not conclusive, and does not justify the refusal of the trial court to submit that question to the jury. Because the trial court in this case refused to submit the question of the reasonableness of the plaintiff's fees to the jury, the judgment in favor of the plaintiff was reversed and the case remanded for a new trial.—*Piggee v. Mercy Hospital, 186 P. (2d) 817 (Okla., 1947).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

*Clinical and Serologic Evaluation of 27,103 Consecutive Slide Tests with Cardiolipin-Lecithin Antigen and Kline Antigen. B. Levine, B. S. Kline and H. Suessenguth. -p. 212.
*The V.D.R.L. Slide Test. A Comparison with the Mazzini, Kahn and Kolmer Tests for Syphilis. D. Widelock. -p. 218.

Standard Test for Syphilis.—According to Kline, a standard test for syphilitic reagin should possess the advantages of maximum specificity, maximum sensitivity, maximum uniformity of results, maximum simplicity and maximum rapidity. An optimal mixture of chemically pure cardiolipin obtained from beef heart and purified lecithin from the same source has been observed in tests for syphilis to give results of maximum sensitivity and of much greater specificity than obtainable with present day antigen extracts; accordingly, it may be used as a base for the *development of a single standard* test for syphilis. Studies showed that cholesterol, isotonic solution of sodium chloride and a certain minimal amount of water to disperse completely the antigen particles should be used in the preparation of the cardiolipin-lecithin antigen emulsion. The reading of results is facilitated by adding glycerin to the antigen. The flocculation reaction, which requires two ingredients and little time, is much better suited for use in a standard test for syphilis than is the complement fixation reaction, which requires five ingredients and much time. The slide flocculation test technic employs concentrated emulsion, optimal ratio of emulsion to serum and mixture of the ingredients on an open glass slide in wax-ringed chambers by rapid rotation. This technic offers more advantages for a standard test for syphilis than does the tube flocculation technic.

Cardiolipin and Kline Antigens.—Levine and his co-workers report a clinical and serologic evaluation of 27,103 comparative slide tests for syphilis with optimal cardiolipin-lecithin antigen and Kline antigen in general hospital and ambulatory patients and in persons presenting themselves for antepartum and premarital examinations. Optimal cardiolipin-lecithin antigen emulsion gave results in the slide test for syphilis of decidedly greater specificity and much greater sensitivity than did diagnostic Kline antigen emulsion and therefore is of greater value than the latter in the diagnosis of the disease. Optimal cardiolipin-lecithin antigen emulsion gave results in the slide test of decidedly greater sensitivity in syphilitic serums and much greater specificity in nonsyphilitic serums than did Kline exclusion antigen emulsion and therefore, when negative, serves better than the latter in the exclusion of syphilis. Optimal cardiolipin-lecithin antigen gave results of maximum specificity and maximum sensitivity in slide tests of the blood of newborn infants of five treated syphilitic mothers. Optimal cardiolipin-lecithin antigen is now being used as the standard antigen for the Kline test. The Kline antigen is employed as an adjunct of confirmatory value.

Venereal Disease Research Laboratory Slide Test.—Widelock compared the Venereal Disease Research Laboratory slide test, which employs a cardiolipin-lecithin-cholesterol antigen, with the Mazzini and Kahn flocculation tests and the Kolmer complement fixation test in 52,372 routine specimens submitted to the Bureau of Laboratories of the New York City Department of Health. The reliability of the Mazzini slide test as a screen test in a large public health laboratory is evidenced by the fact that of 8,425 "negative" Mazzini serums only 74 (0.8 per cent) were reactors to the research laboratory's test. The Kolmer complement fixation test produced approximately the same number of reactors in this group. The relative reactivity of the laboratory's slide, the Kahn standard and the *Kolmer complement fixation tests was 83.6 per cent,* 57.4 per cent and 64.2 per cent, respectively, of the Mazzini reactors tested. Thus the sensitivity of the four tests, in order of reactivity was: the Mazzini slide test, the research laboratory's slide test, the Kolmer complement fixation test and the standard Kahn test.

Electrocardiographic Patterns of Ventricular Aneurysm. E. Goldberger and S. P. Schwartz. -p. 243.

Thymol Turbidity Test in Disease of the Liver.—Kunkel found that in a group of 76 patients with infectious hepatitis who were followed throughout their illness the thymol turbidity test showed a maximal value that was higher than the highest value obtained in a control group of 46 patients. The results would appear to demonstrate the value of this reaction for the diagnosis of acute hepatic damage. No correlation between severity of symptoms and degree of aberration in the thymol turbidity test could be found. The test proved to be of particular use in evaluating persistent symptoms following infectious hepatitis. Patients with cirrhosis of the liver associated with chronic alcoholism showed considerably lower values for the thymol turbidity test than did patients in a non-alcoholic group. Decidedly positive reactions were associated with hyperglobulinemia in various parasitic diseases and other conditions in which an inflammatory process in the liver was present.

Liver Function Tests in Jaundice.—Althausen discusses the pathologic physiology of different types of jaundice and its relation to excretory and metabolic liver function tests. He analyzes the results of the intravenous galactose test and the *response* of prothrombin to vitamin K in the differential diagnosis of the disease of 190 patients with jaundice. He points out the importance of distinguishing between obstructive jaundice, for which surgical operation is the only effective treatment, and parenchymatous jaundice, which constitutes a strictly medical problem. The usefulness of the intravenous galactose test is demonstrated by the fact that, when taken alone, it made possible the *differentiation between obstructive and parenchymatous* jaundice in 3 out of 4 cases. When taken in conjunction with certain simple additional clinical data, this test allowed the identification of the type of jaundice in almost all cases. The diagnostic accuracy of the prothrombin response to vitamin K is shown by the fact that it was present in 9 of 10 patients with obstructive jaundice and was absent in the same proportion of patients with *parenchymatous* jaundice. The author *concludes* that appropriate liver function tests are an important aid in the differential diagnosis of jaundice when taken in conjunction with data from the history, physical observations and other laboratory studies.

Liver Function Studies.—Shay and Siplet believe that adequate liver function studies may be made in jaundice with the following tests: quantitative van *den Bergh, serum* cholesterol partition, *serum* alkaline phosphatase and thymol turbidity. If the physician has only limited laboratory facilities available, he can still follow a case of jaundice by combining the methylene blue test, the galactose tolerance test and the thymol turbidity test. If applied early in the course of jaundice and repeated at short intervals (three to four days for a period of a week; three sets of readings) these tests will usually *permit identification* of the type of jaundice.

Radium and Roentgen in Carcinoma of the Cervix.—Schmitz reviews observations on patients with cervical cancer treated at Mercy Hospital Institute of Radiation Therapy during the ten year period between 1933 and 1942. It was at the beginning of this period that higher voltage roentgen therapy was first introduced at the institute. The plan of radium therapy has remained the same since 1924. A direct comparison of cases for the ten *years of* this study with the cases previously reported would show any advantage gained by the addition of higher voltage roentgen rays. The aim is to attain dose of 4,000 r into the tumor and surrounding gland-bearing areas of the pelvis. Whenever possible only one anterior and one posterior field are used. The size of the field is 20 by 20 cm. or less, depending on the size of the pelvis. The kilovoltage *used is* 800. The focus-skin distance is 70 cm., and filtration is done with lead, tin, copper and aluminum. Although the patients experience intense discomfort at the height of the irradiation effect, the acute cystitis, proctitis and enteritis subside with little permanent injury to these structures. *Inspection of the pelvis in patients with* endometrial carcinoma that has been irradiated similarly and who have been then subjected to hysterectomy has revealed no significant injury to the pelvic viscera. Radium therapy is carried on in conjunction with the roentgen therapy unless the condition of the cervix due to the cancer is such that insertion of radium would *be difficult.* Then the application of radium is postponed until the tumor has regressed sufficiently to make *less* difficult the insertion of radium. Fifty milligrams of radium filtered with 2 mm. brass and 3 mm. of para rubber is placed in the cervical canal for thirty hours. This dose is repeated at seven day intervals for a total dose of 4,500 *milligram* hours. Of the 166 cases reviewed here more than half were inoperable according to present standards. The results obtained with the described irradiation in the groups that were clearly operable were superior to those obtained with surgical treatment in comparable groups. Thus the evidence is in favor of continued radiologic treatment of cancer of the cervix.

Penicillin Vaginal Suppositories to Prevent Postpartum Morbidity.—Pierce says that 778 of 1,573 puerperal women were given 200,000 units of penicillin per vaginam immediately after delivery with a morbidity rate due to infection of the genital tract of only 2.3 per cent. In the control group of 795 cases, the morbidity rate was 5.3 per cent. Blood levels were obtained with intravaginal penicillin in 77.5 per cent of cases on which levels were tested. The authors believe that this administration of penicillin should be of particular value in cases which become morbid after early rupture of membranes and long labor, and in *which* infection of the genital tract is suspected. The routine use of penicillin vaginal suppositories after delivery is justified because of the reduction of the nursing care required in infected cases, reduction in number of extra hospital days per patient and particularly a reduction in genital tract infection following delivery.

Pregnancy and Multiple Sclerosis.—Douglass and Jorgensen say that 5 cases of multiple sclerosis associated with pregnancy have been seen since 1939 at the University Hospital in Baltimore. In 1 of the women the pregnancy was interrupted at the clinic with which the authors are connected, and in another interruption had been carried out elsewhere, although the authors believed that it should not have been done. The other 3 cases would seem to to warrant the conclusion that pregnancy has little if any effect on multiple sclerosis. The disease is one in which remissions and exacerbations normally occur. The progress is not accelerated by pregnancy nor is pregnancy likely to cause exacerbations. In these 3 cases pregnancy proceeded more or less normally; there were no major obstetric complications, and labor was without special incident. All infants were born alive and in good condition and did well. The puerperium was normal and uneventful.

Classification of Cancer of Larynx in Radiation.—Jenkinson and Pirkey present data on a group of consecutive cases of cancer of the larynx in patients treated in the Department of Radiology, St. Luke's Hospital, Chicago, from 1936 to 1945. Of the 58 patients, 45 were available for follow-up study. The authors call attention to the fallacy of radiologists' using a surgical classification. They point out that the classification into intrinsic and extrinsic is important to the surgeon, because any lesion that extends beyond the confines of the larynx cannot be cured by laryngectomy. However, from the radiologic point of view, one can expect as good a result from irradiation in an early lesion of the superior aspect of the aryepiglottic fold as in a similar sized lesion on the true cord. It is the extent of the lesion that is the more important prognostic observation, not the location. The authors present a classification which meets most of the needs of the radiologist. This classification requires a complete examination of the larynx, with direct visualization by means of the laryngoscope, and an adequate biopsy. This should be supplemented by roentgenograms of the soft tissue of the neck. The laryngologist must describe the lesion in terms of the extent of structural involvement, particularly to distinguish between neoplasm and inflammatory reaction. Following this thorough examination and biopsy, the anatomic classification should be determined. A stage 4 lesion may, during proper treatment, shrink to the extent of stage 2, or almost completely disappear, but the records should continue to show it in its original classification. The authors were impressed with the excellent results obtained in early lesions. They found that the earlier in the disease radiation treatment is instituted, the better the result.

Dosage Determination with Radioactive Isotopes.—Marinelli and associates show that when radioactive isotopes are employed either as tracers or in therapy, it is important to be able to determine the radiation dosage. Usually this cannot be measured, but when the half-life, radiation energy and biologic uptake and excretion are known it can be calculated. The paper consists of two parts. In the physical part are given mathematic formulas for dosage rates and total doses for beta ray-emitting and gamma ray-emitting isotopes, together with subsidiary formulas for safe concentration and the like. In the clinical part these formulas are accepted, and doses are considered for specific cases, for a number of isotopes of common interest. Particular consideration is given to the determination of safe tracer doses. Two extensive tables, for beta and gamma rays, respectively, give half-life, radiation average energy, fraction disintegrating per day and specific dosage data, including the safe tracer concentration, for thirty-eight isotope elements.

Meningococcic Meningitis.—Hoyne and Brown review observations on 727 patients who were admitted to the Municipal Contagious Disease Hospital in Chicago with a diagnosis of meningococcic meningitis during the four years 1943 to 1946, inclusive. The ages of the patients ranged from 7 weeks to 71 years. The total fatality rate was 14.8 per cent, but if the 67 patients who were moribund on admission are ruled out, the fatality rate is 6.2 per cent. Sulfonamide drugs were used in practically all cases. Sulfadiazine and sulfathiazole were used in over 500 of the total number; sulfamerazine and sulfapyridine were used in 127 and 68 cases, respectively. There were 103 patients who were treated with penicillin as well as one of the sulfonamide compounds, and 2 patients received penicillin exclusively. The fatality rate was much higher in the group treated with penicillin than in the group treated with the sulfonamide drugs alone. The authors also found that intrathecal therapy is not necessary against meningitis. Moreover, frequent lumbar punctures for drainage are not required. Penicillin is not a valuable adjunct in the treatment of meningococcic infections but is an efficient aid in the management of ocular complications. Although blood sulfathiazole levels are low, there is no doubt in regard to this drug's usefulness for the treatment of meningococcic meningitis. The authors question the emphasis which is customarily placed on the value of blood levels of the drug when considering prognosis.

Psychiatric Aspects of Vagotomy.—Szasz made psychiatric studies on 16 patients who had been operated on for peptic ulcer by vagotomy and in all but 1 of whom the ulcer had healed. The chief object of this study was to find out what happens to the patient as a whole after vagotomy. Over half of the patients were helped by vagotomy. Six patients were found to be unchanged from the psychiatric and clinical points of view; the healing of the ulcer, however, confers protection on these patients against future hemorrhage and perforation. One patient became definitely worse following vagotomy and remained psychologically incapacitated. Discussing the role of psychologic factors in the pathogenesis of peptic ulcer, the author says that patients with peptic ulcer have strong receptive-acquisitive tendencies, which obtain some gratification from the usual medical measures used in the treatment of peptic ulcer; vagotomy brings about healing of the ulcer without providing for these important emotional needs. This explains why some patients insist on continuing with some part of their medical regimen after vagotomy, when the physiologic needs for such treatment are no longer present. Psychoanalysis, although the only etiologic treatment in most cases of peptic ulcer, is not available for the large majority of patients. For those patients who do not respond adequately to the usual medical ulcer regimens and who will not be treated psychoanalytically, vagotomy is probably the treatment of choice. The absence of symbolic oral gratification due to cessation of dietary and other medical measures following vagotomy may be potentially harmful. It is suggested that the clinical results may be improved somewhat if the patients are permitted to continue with certain psychologically meaningful aspects of their preoperative medical regimens after vagotomy.

Streptomycin in Tularemia.—Patients whose case histories are reviewed by Foshay were treated at Cincinnati Hospitals, or their records had been published before or were supplied by physicians. Many patients were treated during years when streptomycin was scarce, and for this reason the composition of the treated group shows a high degree of selection with respect to extensive and severe infections. Streptomycin was usually administered by intramuscular injection every three or four hours, occasionally by continuous intravenous or subcutaneous drips. There was little advantage in the latter procedures. Dosage ranged from 0.015 Gm. every four hours to 0.5 Gm. every three hours, the total dosage varying from 0.64 to 42 Gm. per patient. Fever is commonly in or near the normal range within forty-eight or seventy-two hours. A striking release from headache, mental depression and bodily aches and pains often occurs within the first day. By the third day there is usually a definite reduction in the size of buboes, lessened pain in those regions and in the primary lesions, and occasionally early healing of primary ulcers. Stuporous patients with extensive pneumonic or serosal cavity exudates usually show reversion to mental clarity in from two to five days. Clearing of exudates is usually completed in five to six weeks. Comparison of results obtained with streptomycin and with hyperimmune serum revealed that streptomycin induced better results in most of the major aspects of morbidity even though it was administered later in the course of disease by an average of three days. The disease was shortened about one half by streptomycin therapy. Since dramatic recoveries of some patients in the desperately ill category, have followed the use of 2 to 5 Gm. as total dosage it seems reasonable to conclude that dosage in excess of 10 Gm. is a waste of a valuable product as well as an invitation to toxic and other untoward reactions. There is evidence that a total administration of 2 or 3 Gm. per patient will usually be sufficient. Streptomycin is an extremely effective therapeutic agent against tularemia.

Wounds of Hand.—Mason shows that the surgeon confronted with a serious open wound of the hand is often in a dilemma as to what to do. There may be extensive nerve and tendon division, but the strict indications for primary repair do not obtain. The wound may be seriously contaminated, and there may have been many hours of delay. Regardless of the previous treatment or of the wound's gross soiling, it should be covered at once with sterile dressings and manipulation or inspection should not carried out until it can be done under aseptic conditions. Invasive contaminants come from human sources, the nose and throat and hands of surgeon, assistants, nurses, orderlies, interested bystanders and the patient himself. The wound should be converted into a surgically clean wound at the earliest possible moment and should be covered with voluminous occlusion compression dressing; the hand should be put at rest on a splint. The wound managed in this way has been carried up to the point of closure, and in the early wound would be considered ready to close. In the injury under discussion, it is dressed and splinted and four to six days are allowed to elapse. It is customary to give penicillin during this interval, but a large percentage of patients would do well without it. Secondary closure of the wound may be undertaken if there is no evidence of infection by the fourth to sixth day. After closure the hand is again put at rest on a splint, where it is kept until healing has occurred. Here the universal hand splint is found useful. The hand remains in the position of function during the entire period of healing. Practically every fracture of the hand may be successfully reduced on this splint.

Sodium Bicarbonate in Occupational Medicine.—In the process considered by Probst and Lanahan sodium bicarbonate is used as a powder to keep plastic sheeting from adhering to itself. Although the powder is first applied to the plastic sheeting at room temperature, it is exposed in some parts of the process to a dry heat which may be as high as 190 F. (88 C.) Personnel exposed to the powder in all stages and temperatures of the operation were studied by occasional and annual examinations. The total number studied was 448, representing exposure periods extending from three months to nine years. In 46 employees an eruption of the thoracic and axillary areas and exposed surfaces of the extremities developed. This eruption was a papuloerythematous reaction. In a few cases it extended to exudation and crust formation. Perspiration and friction aggravated the irritation, and scratching superimposed secondary infections in a few cases. The etiologic basis of each case was suggested by appearance of the eruption during the first few weeks of exposure to this powder. All but 2 persons were carried through to skin hardening (as observed by Schwartz) by continuation in the exposure and adherence to hygienic measures. Associated with the dermatitis were changes in hair coloring and texture. Black hair turned brown to brownish red and blond hair was bleached to lighter yellow tints. Texture of hair coarsened and became brittle, but alopecia did not develop. Coincident with cutaneous adjustment, these changes of the hair lost their intensity. Upper respiratory reactions of sneezing, rhinorrhea and dryness of nasal and pharyngeal membrane were passing effects. The hazardous effects of this compound were minimized by an active medical control program.

Vitamin B and Quinacrine Toxicity.—Ershoff found that the administration of toxic doses of quinacrine to immature female rats maintained on a synthetic ration resulted in retardation of growth, alopecia, inhibition of ovarian development, enlarged submaxillary glands, granulocytosis and myocardial damage. These effects were largely counteracted by the addition of desiccated whole liver or yeast to the basal ration and, to a lesser extent, by the administration of additional vitamins of the complex B. Whole liver was more effective than yeast or the additional B vitamins in promoting growth and ovarian development in the immature quinacrine-fed rat. On quinacrine-free rations abnormalities were not observed on any of the diets employed.

Postarsenical Encephalopathy.—Kasdon and Shapiro present histories and postmortem data on 2 women who were treated with neoarsphenamine for asymptomatic syphilis and who died from postarsenical encephalopathy. The first woman, aged 34, was pregnant. Convulsions developed three days after the second injection of neoarsphenamine, and eclampsia was first considered. The authors cite the following factors as decisive in differentiating postarsenical encephalopathy from eclampsia: a positive history of arsenical treatment, usually within three days; no hypertension; no albuminuria; no edema, and no toxic symptoms. The second case, which concerned a woman aged 31, was somewhat less typical than the first. In this patient the symptoms did not appear until fifteen days after the twenty-third injection. The course of the disease and the necroptic changes were typical. Therapy should include sedation and, most important of all, early administration of BAL. Adequate treatment succeeds in lowering the over-all mortality rate from 70 to 11 per cent. The most essential fact in control of this serious complication of treatment with arsenical preparations is the application of therapy before the onset of coma and convulsions. The prodromal symptoms that precede the onset of coma and convulsions are headache, epigastric distress, restlessness and nausea or vomiting, or both. The use of penicillin in the treatment of syphilis during pregnancy may eliminate encephalopathy.

Unusual Complication of Intestinal Intubation.—Brenizer reports a case in which a mercury-weighted Miller-Abbott tube spontaneously coiled and tied itself into a knot in the jejunum proximal to an obstructing omental adhesion. This complication was apparently produced by the use of a flexible tube, previously deformed by long storage in a tight coil. Intestinal tubes should be stored without coiling deformity, and their progress through the intestine should be followed by roentgenologic observations.

Tics as Manifestations of Epilepsy.—Levin reports 3 instances in which tics appeared to be manifestations of epilepsy. All 3 patients manifested epileptic dysrhythmias when they were examined by electroencephalography. The author's opinion that these 3 cases represent atypical forms of myoclonic epilepsy is favored by the electroencephalographic observations of 3 per second spike and wave dysrhythmia, which, according to Lennox, is characteristic of myoclonic epilepsy as well as petit mal and akinetic epilepsy. Tics have a resemblance to myoclonic jerks, and although in the usual forms of myoclonic epilepsy brief contractions of muscles in the upper extremities occur, at times similar contractions of other muscles are seen.

Fatal Acute Pancytopenia Following "Tridione" Treatment.—Carnicelli and Tedeschi describe a fatal case of acute pancytopenia following the use of "tridione" (trimethadione). In this case, as in 2 similar cases reported in the literature, a condition of aplastic anemia accounted for the fatal course of events. No other factor could be incriminated. As in the case reported by Mackay and Gottstein, the hematic condition developed several months after the patient was receiving the medicament; the onset was abrupt and sudden, and no available treatment could prevent the fatal outcome. A note of caution is sounded regarding the administration of this drug and its potential danger, as well as the necessity of frequent examinations of the blood. A plea is made to limit the use of "tridione" to the control of true petit mal seizures.

Morphine Hypersensitivity in Kyphoscoliosis.—Katz and Chandler describe 2 cases exemplifying the adverse effects of morphine on kyphoscoliotic patients with pulmonary cardiac failure. The major physiologic and pathologic factors in the causation of this sensitivity are discussed. The authors do not believe that the exagerated effect from morphine is in any way specific for patients with kyphoscoliosis. Their experience suggests that any patient suffering from long-standing disease of the lung with pulmonary decompensation complicated by heart failure presents similar predisposing handicaps, which might make the added effects of morphine lethal. A sampling of recent case records at the Boston City Hospital of patients with chronic cor pulmonale without kyphoscoliosis lends further support to the impression that these patients are often adversely affected by morphine.

Thrombopenic Purpura Hemorrhagica.—According to Rittershofer, thrombopenic purpura hemorrhagica comprises a group of closely related hemorrhagic diseases characterized by reduction in the number of circulating platelets, prolonged bleeding time, decrease in capillary resistance and spontaneous frank bleeding from mucous membranes and bleeding into the skin causing petechiae and ecchymoses. One group of workers believes that thrombopenic purpura is brought about by hyperactivity of the spleen in destroying platelets. In favor of this view is the benefit obtained by splenectomy. Others stress the view that the cause of chronic thrombopenic purpura is in the bone marrow. This view is based on the observation that all factors which depress the bone marrow lower the platelet count. Thus, agents such as benzene, roentgen rays, radium and bacterial toxins, and neoplastic metastases, all produce a reduction in platelets. Since a severe thrombopenia is almost invariably found in hemorrhagic purpura, one is apt to conclude that the bleeding is dependent on a deficiency of platelets. A study of purpuric cases shows, however, that some patients bleed at a platelet level of 60,000 or higher while others may show only mild purpura with 20,000 platelets or less. The diagnosis of thrombopenic purpura rests on reduction in the platelet count, prolongation of the bleeding time, positive tourniquet test, absent clot retraction and a normal or only slightly prolonged coagulation time. Acute leukemia and aplastic anemia may be confused with thrombopenic purpura, but the appearance of myeloblasts or lymphoblasts suggests leukemia. Examination of sternal bone marrow should leave no further doubt, for a striking increase in immature leukocytes indicates leukemia, and in applastic anemia little regeneration of the blood elements occurs. Infection plays an important role in secondary purpura hemorrhagica. Search for foci of infection is important. Metastases to the bone marrow cause a reduction in the number of platelets. Toxic agents such as benzene and arsphenamine and allergic sensitivity may do the same. For adults removal of the spleen has consistently given good results in thrombopenic purpura. In children, however, splenectomy must be considered as a last resort. There is no justification for subjecting a patient to splenectomy before the most frequent causes of secondary purpura, namely, infection, blood dyscrasias and allergy, are ruled out. Repeated transfusion of blood is effective in idiopathic purpura hemorrhagica. Transfusion just before splenectomy is now the almost universal surgical practice. Ascorbic acid therapy can only be effective in those instances of capillary bleeding in which there is a deficiency of the vitamin.

"Pentothal Sodium."—Sommerfield believes that because of the seeming simplicity of the procedure "pentothal sodium" is being administered by many with immature anesthetic judgment. The casual and infrequent administrator should limit use of this drug to the so-called average case, i.e., one of short duration and in which no special skill is required. Most contraindications to the use of "pentothal sodium" are relative, but the inability to maintain a clear airway, whether that inability arises from the physical condition of the patient, the site of operation or failure of the anesthetist to realize that he is not succeeding in keeping the air passage open, is an absolute contraindication to the use of this anesthetic. The unavailability of oxygen under pressure likewise is a definite contraindication to use of "pentothal." The indications for the use of this agent have increased. Originally it was intended to be a complete anesthetic, but because of its limitations as such, newer technics were developed. Its field of usefulness has been greatly widened by its use in combination with regional, spinal and inhalational agents, and curare. Conditions which only a short time ago were regarded as contraindications to "pentothal" are no longer considered as such. Patients with hepatic disease, in shock, undergoing operations about the oropharynx and nasopharynx or intra-abdominally can be anesthetized with this agent in combination with others.

Cancer of Liver Produced by Butter-Yellow.—According to Sta. Cruz, primary carcinoma of the liver is a problem of the rice consuming people of the Orient. Statistical studies of primary cancer of the liver in Oriental countries show that it has an incidence of 4 to 5 per cent of all cancers, while in Europe and America it is only 0.2 of 1 per cent. The author fed rats with rice to which the carcinogenic agent butter yellow had been added. Butter yellow is p-dimethyl aminoazobenzene. The feeding of albino rats with butter yellow in a diet deficient in vitamin B produced a high incidence of primary carcinoma of the liver or hepatoma. Animals died or were killed in different periods of the experiment, thus it was possible to observe various types of lesions more or less in accordance with the time of survival of the rats. Animals surviving less than thirty days had acute serous hepatitis. Those surviving forty to fifty days showed adenoma of the bile ducts. Fibrosis or annular cirrhosis was observed in those surviving sixty to one-hundred days. Carcinoma or hepatoma was seen in those animals surviving for from one hundred and one to four hundred and sixty-six days. The author points out that the frequency of round cell infiltration in necropsies of supposedly normal livers among Filipinos was interpreted by American pathologists as a reaction of parasitism. The constant observation of this lesion in rats free from parasites can be considered a reaction of vitamin B deficiency in the diet, which is a problem in Oriental countries. The bile duct hyperplasia and adenomatosis (bile duct adenoma), which were prominent lesions of the liver in rats in the first three months of the experiment, may be considered the specific action of butter yellow on the bile ducts of rats, because similar lesions are not encountered in human livers. The 18 cases of carcinoma in this series were all hepatomas originating from the liver cells, none from the bile ducts. The diagnoses of cholangiomas of the liver refer probably to the adenomatous and cholangiomatous type of hepatoma originating from hepatic cells. This is in accord with the high incidence of hepatomas and the infrequent occurrence of cholangiomas in man. Almost all the hepatomas were accompanied or rather preceded by annular cirrhosis of the portal type. This is also observed in human hepatomas. The presence of cirrhosis is a reliable differentiating point in favor of hepatomas. Cirrhosis is seldom seen in metastatic carcinomas of the liver in man.

Malignant Lesions of Uterus Associated with Ovarian Tumors.—Mussey and associates point out that the association of malignant lesions of the uterus with estrogen-producing neoplasms of the ovary has been noted by several writers and suggests the possible importance of the estrogens as carcinogenic agents in the human female. They present the histories of 2 patients recently observed at the Mayo Clinic in whom functioning ovarian tumors concurred with malignant growths in the uterus This report brings to 15 the number of malignant lesions of the uterus which have been found in conjunction with the 87 estrogen-producing ovarian neoplasms observed at the clinic. Data on 62 granulosa cell tumors and 23 theca cell tumors have previously been reported. The incidence of malignant lasions of the uterus in the combined series is 17.2 per cent. These figures are in close agreement with Hertig's estimate that 18 to 20 per cent of granulosa cell tumors are accompanied by carcinoma of the uterus. The experimental evidence to support the contention that carcinoma of the uterus may be produced by estrogens is suggestive but not conclusive. In the human being several clinical and pathologic observations sustain the belief that endometrial malignant lesions fail to develop without accompanying hyperestrinism. Etiologic factors other than the estrogens have been considered by those who have studied carcinoma of the body of the uterus; these include fibromyomas and radiation.

Allergic Gastric and Duodenal Edema.—Friesen and his co-workers sensitized dogs locally by immune horse serum of high antibody titer, either by direct mucosal and submucosal infiltration or intra-arterial injection. (The horse from which the serum was obtained had been sensitized previously to five different antigens.) After one to ten days one of the antigens to which the dog thus had been sensitized was injected systemically via a vein of the tongue and measurements of the viscus wall thickness and biopsies were obtained before and after injection of the antigen up to ten hours. All dogs thus sensitized manifested gross and microscopic edema following systematic intravenous injection of antigens. In dogs in which sensitization of the duodenum was accomplished by injecting immune horse serum within the duodenal lumen mucosal edema also developed after systemic injection of antigen. All five antigens were observed to be effective in initiating the response. One series of dogs was subjected to the same procedures with normal horse serum having a negative antibody titer to the antigens employed instead of the prepared horse serum with high antibody titer; these dogs had no edematous reaction after intravenous administration of antigens. To evaluate the role of allergic edema on the provocation of ulcer, a number of dogs were sensitized in the manner described. Forty-eight hours after sensitization, daily intravenous injection of the antigen into the systemic circulation of the dogs was begun; a different one of the five antigens to which the horse had been sensitized was injected daily until all five foreign proteins had been administered (a total of five days). In one series a mixture of histamine in beeswax was injected intramuscularly each evening. Another series of dogs was subjected to the same procedures with normal horse serum having a negative antibody titer to the antigens employed instead of the prepared horse serum with *high antibody titer. All the dogs subjected to the* production of local anaphylaxis with concomitant administration of the mixture of histamine in beeswax demonstrated edema with ulcer and/or erosion at the site of sensitization at the time they died or were killed (five days or less). Three of the six dogs subjected to the production of local anaphylaxis without administration of histamine in beeswax demonstrated definite ulcers at the site of edema after five days of antigen administration; all 6 showed edema at the site of senstitization. Of the dogs subjected to local injection of normal horse serum of negative antibody titer followed by daily systemic injection of antigen accompanied by the administration of histamine in beeswax, none showed edema, erosion or ulcer. Experimental gastrointestinal edema resulting from local antigen-antibody reaction favors the development of the histamine-provoked ulcer in dogs and abets the ulcer diathesis.

Nonspecific Ulcers of Small Intestine.—Evert, Black and Dockerty review 130 cases of primary jejunal and ileal ulcers in 97 men and 33 women. The average age of all patients was 43 years. Nonspecific localized ulcerations of the jejunum and ileum are so similar pathologically as to justify their classification as a group under the name *primary, or simple, ulcers. Although the lesions* are characteristically solitary, small groups of ulcers are sometimes observed. The causation of primary ulcers is unknown. There is little direct evidence to support theories that they are caused by infection, irritation from gastric secretions, trauma or vascular abnormalities. The symptoms of primary ulcer are for the most part secondary to the complications of perforation, bleeding or obstruction. The possibility of these lesions should be considered in the presence of unexplained intestinal bleeding or of peritonitis which suggests acute visceral perforation when such perforation cannot be found in the stomach or duodenum. *The mortality rate is high;* there were 56 fatalities among the 85 cases recorded before 1931, and 21 deaths among the 45 recently occurring cases. The lesion has been recognized during life only after some complication has led to surgical intervention.

"Demerol" and Opium Alkaloids in Biliary Spasm.—Gaensler and his co-workers made pressure studies which included determination of resting intrabiliary pressure, perfusion pain level and pressure changes resulting from the action of meperidine hydrocloride "demerol hydrochloride" N.N.R and opium alkaloids, in 10 postoperative patients with T tube *biliary drainage. Results in 10 unselected* patients with T tube drainage of the common duct showed that, contrary to common belief, meperidine is to be considered as a spasmogenic rather than a spasmolytic agent on the sphincter mechanism at the lower end of the common bile duct (Oddi). The spasm produced was intermediate in intensity between that produced by codeine and that by *morphine;* it was sufficiently severe in 2 instances to initiate a typical attack of biliary colic. The drug was observed to increase rather than relieve natural duodenal spasm as well as spasm produced by codeine. The effect produced by meperidine was regularly but briefly relieved by amyl nitrite or aminophylline. Meperidine should be used with as much caution as the opiates in postcholecystectomy pain. If biliary colic is due to spasm, glyceryl trinitrate 1/250 grain (0.25 mg.) in doses of one to two granules under the tongue will relieve the attack. If the pain is due to biliary obstruction other than spasm relief will not be afforded by the nitrites and morphine or meperidine.

"Sulfasuxidine" and Streptomycin in Urinary Infections.—Crowley and O'Conor say that the apparently complete cure of a highly refractory urinary infection following treatment with sulfasuxidine (succinylsulfathiazole) plus streptomycin prompted them to use this combination in 23 patients, who had been under observation for from three months to twenty years without an effective or lasting eradication of the colon bacillus from the urine. The results have been so uniformly successful, and so much more noteworthy than when streptomycin alone was employed, that the authors believe this combination to offer the possibility of an effective method of cure in a greater percentage of these resistant cases than has been obtained by other methods of medication heretofore employed. Of 23 treated patients, 19 have maintained a completely favorable response for periods sufficiently prolonged to suggest a permanent cure. These patients received succinylsulfathiazole for varying periods before, during and after the administration of 5 to 17 Gm. of streptomycin. Either agent given alone had not had the favorable effect observed in the combined therapy. Success in the 19 patients with longstanding resistant infection seemed dependent on the patient's ability to continue the ingestion of succinylsulfathiazole. Fortunately the toxicity of the drug is low, and it can be given in large doses for long periods of time. Toxic symptoms, if they occur, subside rapidly when administration of the drug is discontinued.

Mother-Child Incompatibility Problem in Relation to Nervous Sequelae of Hemolytic Disease of Newborn. D. F. Cappell.—p. 486.

Early Traumatic Epilepsy.—The material studied by Whitty falls into two groups: First, 29 cases of early epilepsy occurring among 434 consecutive gunshot wounds of the brain observed twelve to forty-eight hours after wounding; second, 23 cases found among the records of some 400 patients with brain wounds evacuated to a base hospital within a few days of wounding. Early epilepsy of a motor type only was recorded. The phrase "early attacks" is used here in a physiologic rather than a purely temporal sense. Attacks that occurred while the clinical condition of the patient and the state of the wound suggested that brain edema, local vascular change or actual brain debris were still present, were considered as early. Such a definition seems comparable to the usually accepted "first few days." The author made an attempt to evaluate the importance of traumatic factors such as site and severity of wound and constitutional factors such as family and personal history of epileptic phenomena in these early attacks. It is concluded that site plays little part in their incidence, though it may influence the type of attack which occurs. Extent of surface damage may be important, and constitutional factors are significant. The follow-up in these cases shows that they involve a greater likelihood of later epilepsy than similar wounds without early attacks. Late attacks occur both with and without involuntary movements.

Pruritus Vulvae from Rubber.—Clarke reports the case of a woman aged 27, in whom pruritus vulvae followed the use of rubber condoms. The irritant was traced to the presence of free alkali from potassium oleate used in the manufacture of the sheaths as a stabilizer. Soaking of the sheaths in a 0.5 per cent solution of sulfuric acid for twelve hours proved satisfactory. It is remarkable that the action of alkali on this woman's skin appears to be that of allergic sensitization rather than simple chemical damage.

Homologous Serum Jaundice.--Scott and Tovey relate the clinical history of a primipara, aged 19, who was jaundiced when she was hospitalized for an abscess in the breast. The jaundice had begun fourteen days previously. Because of a postpartum hemorrhage the patient had received a transfusion of two bottles of plasma and one bottle of group O Rh-negative blood seventy-nine days before the onset of the jaundice. The relatively high incidence of hepatitis following plasma transfusions (5 to 10 per cent) make it seem probable, therefore, that this was a case of homologous serum jaundice. Fortunately this patient made a complete recovery.

Homologous Serum Jaundice in Infancy.--Apley and Wallis describe 2 fatal cases of homologous serum jaundice in infants. In 1 child jaundice developed sixty-three days after the infusion of plasma; the infant died at the age of 5 months after a short illness characterized by vomiting and convulsions. The other child was 1 year of age when jaundice developed one hundred and twenty-two days after infusion; he died after four days' illness, having been comatose for two days. No other cases of jaundice could be traced in 17 babies who had also been treated with intravenous plasma, or in 5 babies treated with intravenous saline solution or whole blood.

*Brodie's Abscess of Tibia: Its Treatment by Surgery. Penicillin and Sulfadiazine. S. Scott and F. S. Preston. -p. 296.

Aftermath of Gastrectomy.—Surveying the treatments that have been employed against peptic ulceration during the present century, Lake *believes* that at present gastrectomy gives better and more permanent results than most other surgical or medical treatments. He reviews observations on 615 patients whom he treated in the course of twenty-three years. A type of end to side anastomosis with a restricted and valvular orifice has been found to give good results in the vast majority of cases. The risk of the operation is being steadily reduced, chiefly as a result of greater preoperative and postoperative care. Sulfonamide therapy, used as a routine, has proved valuable in the prevention of infective pulmonary complications. Omental necrosis and early morning nausea are noted as results not previously described. The incidence of anastomotic ulceration after this operation appears to be a little under 1 per cent. Discussing the syndrome of postoperative hypoglycemia associated with a "dumping" stomach, the author cites a report by Gilbert and Dunlop, who observed it in no fewer than 17 among 45 gastrectomies. In his own material the incidence was much lower, only 20 in 615 cases. He feels that this problem is not yet completely understood and in searching for the cause he considers four possibilities: (1) dumping of the stomach contents into the jejunum with reflex effects, via the splanchnic innervation, from overdistention; (2) hypoglycemia; (3) vagus stimulation and neurosis. Other postoperative complications discussed are morning nausea, adhesions, ventral hernia, gallstones and colospasm.

Brodie's Abscess of Tibia.—Scott and Preston report the case of a man aged 52, who complained of intense, continuous, deep-seated pain situated in the lower end of the tibia. There was a history of a compound fracture of the lower third of the left tibia and fibula some thirteen years previously. This fracture had united, but there was considerable thickening of both the tibia and fibula at the junction of the middle and lower thirds. Gross swelling of the left ankle was seen, particularly over both malleoli, where two large abscesses were pointing and appeared to be about to rupture. Lymphangitis was pronounced up to the level of the knee. Radiographic examination revealed an egg-shaped cavity of the lower third of the tibia, about 2½ inches (6.35 cm.) long vertically, by about 1 inch (2.5 cm.) in breadth and in depth. There was a small beadlike pocket connecting with the lower aspect of the cavity. The whole was surrounded by dense sclerotic bone. A diagnosis of Brodie's abscess was made. The superficial abscesses were aspirated, and sodium penicillin was injected into each abscess. Repeated aspiration of the superficial abscesses, introduction of penicillin and systemic treatment with sulfadiazine and penicillin resulted in cure of the superficial abscesses. The bone was saucerized over the abscess and the bone chips were preserved in warm isotonic solution of sodium chloride. After exposure of the lining membrane of the abscess all further bone chips were discarded. The abscess was fully laid open along its whole length, and the gray pus which formed its contents was removed and retained for examination. The lining membrane was carefully curetted with a Volkmann's spoon and all debris removed. The cavity was then packed with the previously preserved bone chips. An ordinary wide bore intravenous needle was introduced into the cavity. The dressing was arranged so that the base of the needle would protrude through the dressing without interference with the wound itself, thereby enabling injections of penicillin to be carried out at three hour intervals. Bacteriologic examination of the pus from the bone abscess revealed numerous gram-positive cocci, which on culture gave profuse colonies of Staphlyococcus aureus pyogenes. This operation resulted in obliteration of the bone cavity with healing of the wound by first intention and retention of the shape and symmetry of the limb.

Cerebral Symptoms of Thromboangiitis Obliterans.—A man aged 29 came to Perk's attention when the man's clinical documents were under scrutiny for consideration of his claim to a pension. The fact that in the sixteen and a half months during which this man was under observation his disease was variously diagnosed as schizophrenia, mania, manic-depressive psychosis and epileptic psychosis, all as primary conditions, even though the condition of his feet was correctly diagnosed as due to thromboangiitis obliterans, indicates that the occurrence of cerebral manifestations of thromboangiitis obliterans is seldom considered. It is possible, of course, that the mental condition was not connected with the vascular one. Other authors have warned against too readily assuming a connection between the two, but the occurrence of other cerebral manifestations such as fits, diplopia and dysarthria, the earlier paroxysmal sypmtoms typical of thromboangiitis obliterans affecting the cerebral vessels, points to the probability that mental symptoms were likewise due to the vascular condition. The literature provides evidence that neurologic symptoms may be produced by thromboangiitis obliterans of the cerebral vessels. There may be muscular spasms ranging from tics to epileptiform convulsions; palsies ranging from weakness to complete paralysis, either localized to a group of muscles, commonly in the face or in an extremity, or affecting half the body (hemiplegia); sensory disturbances such as hemianopia and numbness; speech disturbances, and impairment of higher cerebral functions. In addition, mental symptoms may range from transient confusion or excitement to full fledged psychoses. Neurologic and mental symptoms may precede, though more commonly they follow, manifestations of the disease in the extremities and other parts of the body. The author discusses several views on the pathogenesis of this condition.

*Infective Hepatitis. J. Mackay-Dick. -p. 290.

Infective Hepatitis.--Mackay-Dick discusses an outbreak of fulminating hepatic necrosis affecting essentially soldiers of the Polish forces of the British Army of the Rhine. At least 32 of the total of 38 patients who died are known to have had syphilis and antisyphilitic therapy. The likelihood of syringe transmission of the disease is suggested. The author stresses that of 154 patients with infective hepatitis dealt with in one British Military Hospital 89 had venereal disease and a total of 117 had had injections of some sort during the preceding six months. In the fatal cases in which the brain was examined cerebral edema was evident. Adequate sterilization of all needles and syringes used in protective inoculations and in the transmission of all fluids into the human body is of vital importance.

Quinine and Congenital Ear and Eye Defects.--Winckel says that some authors have ascribed congenital defects of the eye and ear in children to the fact that the mothers took quinine during pregnancy. It is by no means sure that quinine was the cause of these defects. The literature reports only 17 cases of this type, and these congenital defects appear to be no more numerous and serious whether the use of quinine has been excessive or moderate. Deafmuteness is no more frequent in endemic malarial states with a large consumption of quinine than in states without malaria where the amount of quinine used may be negligible. The 17 cases mentioned in this paper were published before there was any suspicion concerning the deleterious influence of rubella in the mother on the fetus.

Rational Treatment of Plantar Warts.--McLaughlin calls attention to the dangers involved in treating plantar warts with roentgen rays or radium and describes a combination of curettage and diathermy, which he has found effective. He pares down the overlying horny skin until the typical bundles of the wart are clearly defined. A Volkmann spoon, the exact size of the wart, is then driven into the foot at the edge of the wart, and swept round so that the core is shelled out complete. The hyperkeratinized collar at the neck of the cavity is trimmed with scissors, and the hole converted into a "saucer." The base, which is tough, must then be scraped until smooth and repeatedly touched with a diathermy needle or an electric cautery, using a fine point with a light touch. A small wick of ribbon gauze is inserted into the cavity and the area covered with gauze and elastoplast. The patient can usually walk with care immediately; and, after the plug has been removed in forty-eight hours, there should be little discomfort. Healing is usually complete in seven to ten days. A case is presented which illustrates both the detrimental effects of roentgen treatment and the wide scope of the described procedure.

Clicking Pneumothorax.—Fox is concerned with the striking and dramatic physical sign termed by some observers pericardial knock, which consists of a clicking noise synchronous with the heart beat and often audible at some distance from the patient. The author cites earlier reports of cases of this type and describes 2 new cases. It has been observed in spontaneous as well as in artificial pneumothorax. The possible mechanisms of production are critically analyzed. It is suggested that the click is produced in a free pneumothorax space by the impact of the lingula against the anterior chest wall, its movement being initiated by the cardiac impulse. The production of the click in this manner has been confirmed in the cadaver.

Blood Transfusion and Rh Sensitivity.—Davies states that a man aged 31 was given 4 pints (1.9 liters) of blood over a twenty-four hour period, because he had an extremely low hemoglobin content following vomiting of blood and having black stools. After the transfusion the patient became jaundiced. Examination of his blood revealed gross hemolysis. Further questioning revealed that he had received 20 cc. of malarial blood by intramuscular injection at a malaria experimental station in January 1944. The patient's blood was found to belong to group O (IV) and to be Rh-negative. The patient was apparently made sensitive to Rh-positive blood by the intramuscular injection of 20 cc. of blood in January 1944, there being no history of previous blood therapy. Although the patient's serum and the donors' cells were compatible at room temperature for twenty minutes, the transfusion subjected him to a grave risk. For absolute safety, either of the following precautions should be taken if there is a history of previous blood transfusion or intramuscular injection of blood: (1) the blood should be tested for the Rh factor, and if it is Rh-negative, the patient should be given Rh-negative blood; (2) the cells of the donor's blood and the patient's serum should be incubated at 37 C. for twenty minutes before being pronounced compatible.

•Investigations on Etiology of Reiter's Disease or the Conjunctival-Urethral-Synovial Syndrome. E. Pastinszky. -p. 415.

Reiter's Disease.—Pastinszky reviews the earlier literature on the syndrome characterized by arthritis, urethritis and conjunctivitis, which was first described by Reiter in 1916. He reports 7 cases of this syndrome seen in a group of soldiers during World War II. The syndrome was preceded three or four weeks by diarrhea. Bacteriologic examination of the feces was impossible, but in 2 cases serologic tests revealed agglutinations of 1:200 to 1:400 with strains of Bacterium flexneri. The conjunctival and urethral secretions did not yield dysentery bacilli, spirochetes or virus. The Frei test for the virus of lymphogranuloma inguinale was negative. The syndrome must be considered as a specific allergic or para-allergic reaction after an intestinal bacillary infection, in which the reacting organs are the urethra, the bladder, the conjunctiva and the joints with eventual involvement of other organs. The allergic pathogenesis is partially confirmed by tests on the mucous membranes or by other allergic phenomena such as urticaria, leukopenia, local eosinophilia (conjunctival and urethral secretions) and general eosinophilia in the blood. The disease may be accompanied by severe generalized syndromes, such as remittent fever, or a subfebrile state. The blood formula shows deviation to the left and in certain cases eosinophilia. The arthropathies are refractory to treatment with sodium salicylate or phenylquinoline. Various antiallergic measures such as fever therapy, autohemotherapy, calcium and ephedrine and dextrose have been effective.

Penicillin Therapy in Diphtheria. S.J. Wszelaki and L.J. Handzel.—p. 493.

Types of Diphtheria Bacillus and Clinical Aspects.--Ammundsen and his associates report that during the winter of 1943-1944 a total of 403 patients with diphtheria were treated at the Blegdam Hospital in Copenhagen. The fact that 70 per cent of the patients were adults is regarded as due to the fact that 90 per cent of the school children have been inoculated against diphtheria since 1941. Of 299 cases in which the diphtheria bacilli were typed, the organism proved to be of the mitis type in 133 and of the gravis type in 141. Of those with a mitis infection 6 per cent died and of those with a gravis infection 14 per cent died. The incidence of severe cases was 15 per cent in the mitis group, 27 per cent in the gravis group. Of 112 patients with mild diphtheria none died. There was one death among 164 patients with moderately severe diphtheria, but no less than 20 deaths in the group of 64 severe cases. Thus, severe diphtheria in spite of early and large doses of antitoxin is still a rapidly progressive disease, with a death rate of 30 per cent. Nearly three fourths of the patients in whom diphtheria developed had not been vaccinated; 62 had had one or two injections, and only 44 had been adequately inoculated with three injections. Whereas 22 per cent of the unvaccinated patients belonged to the group with severe diphtheria, the incidence fell to 5 per cent among those partially vaccinated; only 2 fully vaccinated patients had severe diphtheria. Not a single patient who had been adequately vaccinated died from diphtheria.

•Effect of Methylthiouracil on Histologic Picture of Thyroid Gland in Hyperthyreosis. C. Wegelin. -p. 3.
•Treatment by Intra-Arterial Injections. A. Kappert. -p. 25.
Tuberculous Morbidity in a Training-School for Nurses and Primary Results of Systematic Vaccination with B. C. G. by Scarification of Skin. A. Delachaux. -p. 42.
•Hemopsonins; Phagocytosis of Erythrocytes in Peripheral Blood. W. Baumgartner. -p. 61.

Methylthiouracil in Hyperthyreosis.—Wegelin treated 31 patients with hyperthyreosis with methylthiouracil ("thiomidil") prior to doing partial thyroidectomy. Twenty-nine of the patients were women between the ages of 22 and 66 and 2 were men aged 48 and 37, respectively. The clinical picture varied from severe diffuse toxic goiter to mild hyperthyreosis. The daily dose of the drug varied from 0.0375 to 0.375 Gm. In the majority of the cases treatment was continued for two to three weeks but in some cases for longer periods up to six months. The smallest total dose was 1 Gm. in five days; the largest, 27.5 Gm. in ten weeks. Microscopically, the removed thyroid tissue was not uniform. A more pronounced epithelial proliferation did not correspond with the administration of larger doses of the drug. The thyroid tissue of the patient who received the largest total dose of the drug showed the greatest abundance of colloid. Epithelial proliferation was not evident in all cases, and a considerable number of cases were conspicuous for their high colloidal content. These differences cannot be explained by the additional administration of iodine, which was given in only 6 cases, or by the dosage and duration of treatment with methylthiouracil. The chemical examination of some of the removed thyroids suggested that methylthiouracil may reduce the synthesis of thyroxin. Loosening of epithelium, nuclear pyknosis and colloidal atrophy of the thyroid was demonstrated on microscopic examination of the thyroid tissue of rats which were given methylthiouracil; regeneration was suggested by the frequent occurrence of mitosis.

Intra-Arterial Injections.—According to Kappert, treatment by intra-arterial injections is principally indicated for disturbances of the peripheral blood circulation to control arterial spasms. Drugs best suited for this purpose are those which act on the autonomic nervous system, i.e., on the vegetative innervation of the blood vessels. In addition to such drugs as procaine hydrochloride, 2-benzyl-2-imidazoline ("priscol"), acetylcholine and "embran" (muscle extract), intra-arterial injections of calcium (calcium gluconate in a 10 to 20 per cent solution) have been used for circulatory disorders at the medical policlinic in Bern. In a man aged 65 with arterial embolism, paresthesis in the left arm subsided and pulsation at the bend of the elbow and in the radial artery was restored after eight injections of 10 cc. of 10 per cent solution of calcium into the brachial artery. In a woman aged 23 with lymphedema of the leg, the swelling subsided after the intra-arterial injection of 10 cc. of a 10 per cent solution of calcium three times a week for two weeks. Combined intra-arterial injections of 50,000 units of penicillin with 10 cc. of a 10 per cent solution of calcium gluconate in addition to one intramuscular injection of 150,000 units of penicillin daily (one series of ten injections) are recommended for lymphedema of inflammatory origin, for acute attacks of inflammation of connective tissue and for lymphangitis. Intra-arterial injections of penicillin combined with a vasodilator ("priscol") proved effective in cases of necrosis and gangrene associated with functional and organic disorders of peripheral vessels. Cramps in the calf on walking and feeling of heaviness in the left leg in a man aged 66 subsided after seven injections into the femoral artery of nicotinamide combined with nicotinic acid. In cases of vascular spasm, therapeutic trials with intra-arterial injections of 0.5 to 1 mg. of dihydroergotamine showed that this drug is a vasodilator causing dulness of the sympathetic tonus.

Hemopsonins.--According to Baumgartner, leukocytes that ingest erythrocytes present a rare species of cells of the peripheral blood. Hematologic reports in the literature show that these phagocytic cells may be observed in relationship with certain hemolytic syndromes but also in the course of bacterial diseases, particularly in sepsis lenta and in certain intoxications. The phagocytosis of the erythrocytes in the peripheral blood as well as in the reticuloendothelial system results from a preceding "opsonization" of the red blood cells. Experiments demonstrated that an opsonic effect may be produced by the rhesus antibodies in addition to that produced by the antibodies which are specific for the blood groups. Consequently, phagocytosis of the erythrocytes may be interpreted as a *symptom of the two morbid conditions* which are related to the isoantibodies, i.e., the accidents occurring after the transfusion of blood from donors whose blood groups and Rh factors are different from those of the recipients, and fetal erythroblastosis. The autoantibodies which are responsible for certain hemolytic diseases behave like the isoantibodies. They are able to act not only as agglutinins and hemolysins but occasionally as opsonins. This has been confirmed by clinical observations of phagocytosis of erythrocytes in acute hemolytic anemia and in paroxysmal hemoglobinuria. Phagocytosis of the erythrocytes occurred in infectious diseases such as streptococcicosis and in certain intoxications. It is suggested that the microbes in question or their toxins and certain hemolytic poisons may exert an opsonizing effect. Phagocytosis of the abnormal blood cells of sickle cell anemia and pernicious anemia may occur in the peripheral blood without a preceding opsonization, and it may be due to the pathologic condition of the surface and the shape of these cells. The observation of erythrocyte-containing cells in blood specimens suggests that one should watch for antibodies specific for erythrocytes or for poisons and micro-organisms which are known to be harmful to the red blood cells.

Intraocular Tuberculosis. K. A. Reiser. -p. 1.
When to Perform a Prophylactic Attachment of Retina. F. Fleischer. -p. 29.
*Changes in Fundus Oculi in Panmyelophthisis: Pathogenesis of Detachment of Retina. H. Krümmel. -p. 39.
Retinal Vessels in Hypotension. A. Jäger. -p. 44.
*Involvement of Eye in Typhus. G. Wilhelm. -p. 48.

Detachment of Retina in Panmyelophthisis.--Krümmel reports the case of a woman, aged 26, who died of severe anemia which was refractory to all treatment and in which all blood cell systems were destroyed. In the terminal stage multiple necrotic and hemorrhagic processes were visible in the eyegrounds and there was secondary detachment of the retina. On the basis of microscopic observations in the course of necropsy, the author discusses the currently accepted theory of detachment of the retina by cystic degeneration and subsequent rupture and raises the question of "detachment of the retina without tear." Microscopic details show that as a rule it is not the entire retina with its pigment epithelium that becomes detached from its base, but only the true retina from the pigmented layer. Discussing the topography of retinal hemorrhages, the author says that all three forms are really intraretinal and the terms subretinal and preretinal do not correspond with the microscopic observations. It would be more correct to speak of deep and superficial hemorrhages and to designate the third kind as interstitial hemorrhage.

Involvement of Eye in Typhus.--According to Wilhelm the eyeball may be involved in typhus. Typical nodules have been detected in the arteriolar walls of the orbital tissues and of the rectus muscles of the eye. The initial conjunctivitis of spotted fever is caused by roseola of the conjunctiva. The involvement of the cornea in typhus is always secondary. The nodular iritis usually subsides completely. In the choroid the vascular wall nodules are found chiefly in the arteries in the layer of the medium and larger vessels. The retina either shows secondary changes in the form of circumscribed detachment of the retina and retinal edema over the choroid foci or shows the typical nodules in the retinal arteries near the papilla. The involvement of the optic nerve in typhus takes the form of diffuse infiltration of the arachnoidal sheath and of the endoneural septums; typical vascular wall nodules are found in the central artery. The most frequent change of the fundus oculi in typhus is the prominent papilla, which is usually interpreted either as incipient choked disk or as optic neuritis. Circumscribed infiltrations of choroid and retina, the latter connected with a retinal artery, are also eyeground changes typical of typhus. Arteriolar changes near the papilla, which appear early in typhus, are most probably the result of perivascular infiltrations. Hemorrhages which are observed in the nerve fiber layer probably result from the venous stasis that accompanies optic neuritis or from the venous thrombosis that is brought on by the lowered blood pressure. Most changes in the fundus oculi subside without sequelae in several weeks. The only lasting complication is postneuritic atrophy of the optic nerve, but this is rare.

Penicillin Treatment of Subacute Bacterial Endocarditis. A. C. Taquini and B. B. Lozada. -p. 417.

Penicillin in Subacute Bacterial Endocarditis.--Taquini and Lozada resorted to penicillin therapy in 7 cases of subacute bacterial endocarditis caused by streptococci of the viridans group. The patients were between the ages of 15 and 30 years. The previous cardiac disease was rheumatic fever in 6 patients and congenital heart lesion in one. Clinical and bacteriologic recovery was obtained in 6 cases. Repeated blood cultures made at intervals of four or five days offer the most efficient method for regulating the adequate dosage of penicillin and observing the course of the disease. The initial daily dose was 500,000 units. Negative blood cultures by the end of the first week of treatment, indicated that the daily dose was adequate and that it should be administered for at least four consecutive weeks. Positive blood cultures after the first week of administration of 600,000 units of penicillin a day indicated progressive increase of the dose. The dose was then maintained for at least twenty-one days. Daily doses of from 600,000 to 1,200,000 units of penicillin were required in 3 of the 7 cases. The authors prefer intramuscular injections at three hour intervals. Continuous intravenous administration of penicillin with heparin is inconvenient and painful. The trocar for intravenous administration produces edema of the walls of the veins and their consequent obstruction.

*Chemotherapy of Diseases of Biliary Tract. K. A. Lämmli. —p. 81.
Measures Against Resistant Tuberculosis. H.O. Pfister. —p. 92.
Significance of Tuberculin Reactions in General Evolution of Tuberculosis. P. Press.—p. 95.

Chemotherapy of Diseases of Biliary Tract.--Discussing the difficulties encountered in the diagnosis of diseases of the gallbladder, Lämmli stresses the use of duodenal aspiration, which has diagnostic as well as therapeutic value. The important factors in the treatment of diseases of the biliary tract are combating infection and biliary stasis, and protection of the liver. Nicotinamide is the most promising hepatotropic substance to serve as a vehicle for antibacterial substances. The author mentions a substance (bilamid) that has been synthesized on the basis of this reasoning and which in experiments on animals showed a decided antibacterial and choleretic action and at the same time retained the pellagra-preventive action of the nicotinamide. The efficacy of the new therapeutic preparation was proved on 31 patients in whom the biliary flora was studied bacteriologically and culturally. The preparation was employed in 221 patients of whom 152 had inflammatory diseases of the biliary tract. It proved valuable not only in the biliary disorders but in acute enteritis. Effects varied in conditions like duodenal ulcer, gastroduodenitis and ulcerative colitis. The preparation can be given by mouth or intravenously. In serious cases the oral and intravenous therapy can be combined.

*Succinic Acid Stimulating Respiration. M.R. Castex, L.E. Camponovo and F.E. Labourt.—p. 195

Succinic Acid Stimulating Respiration.--Twenty patients with anoxia and 3 normal persons were given an intravenous injection of 5 cc. of a 1 per cent succinic acid solution. The respiratory rate was determined before and after administration of the drug. Greatly improved respiration was observed both in normal persons and in patients. The rhythm of respiration improved in all cases of anoxia, with a tendency to become normal. Oxygenation of blood in the lung also improved, as the blood showed a better saturation with hemoglobin. The drug did not cause any change in the arterial pressure or any other unpleasant reaction. Improvement in respiration in patients with anoxia lasted for more than forty-eight hours in 14 patients and for more than one hour in 7 patients.

*Administration of Ouabain in Aerosols. A. Ravina, A. Feder, M. Nory and J. Servier. -p. 93.
*Efficacy of Penicillin in Scarlet Fever and Its Complications. T. Jersild. -p. 93.
Diagnosis of Primary Tuberculosis of Cervix. P. Normand and P. Labignette .-p. 95.

Administration of Ouabain in Aerosols.--According to Ravina and his associates the cardiac stimulant ouabain is ordinarily administered by the intravenous route. If prolonged treatment is required, this will involve many injections, which may cause considerable difficulties, particularly in obese and edematous women, in whom the superficial venous network is not especially evident. It has been demonstrated that cardiac stimulants administered in the form of aerosols can be absorbed by way of the respiratory tract. Sixteen drops of a 1 per cent solution of ouabain in a glycerin-alcohol medium given in aerosol form proved as effective as the intravenous injection of 0.25 mg. of ouabain. Many patients with cardiovascular defects were treated in this manner. The authors present 5 illustrative case histories. It is sufficient to employ the aerosol once or twice a day for a few minutes.

Penicillin in Scarlet Fever.--Jersild says that at the Blegdam hospital in Copenhagen 100 patients with scarlet fever have been treated with penicillin since December 1945. Results show that a daily dose of 90,000 to 150,000 units, depending on the age of the patient, is sufficient to clear the nose and throat of streptococci in forty-eight hours. Two injections a day should be continued for six days. The higher concentrations obtained with injections every three hours are not necessary. With the two daily injections the angina is rapidly healed and the fever persists for only four or five days instead of seven days as in the cases treated with sulfonamide drugs. The average hospitalization was only eight days. Complications in the form of otitis and nephritis were never observed, whereas formerly a considerable number of patients with scarlatinous otitis required mastoidectomy.

*Blood Groups and Tissue Groups. G. Oliva and D. Furbetta. -p. 414.

Blood Groups and Tissue Group.—The authors observed that intravenous injections of juice from gastric mucosa in the therapy of hypochromic anemia caused in some cases symptoms similar to those from incompatibility of blood groups. Then they carried out experiments. The material consisted of large portions of resected stomach from patients with either gastric or duodenal ulcers, from which juice was prepared. The juice was unmistakably free from traces of blood serum. The technic for preparation of the juice is described in detail. It was found that both the blood serum of the donor of the gastric mucosa and the juice of the mucosa agglutinated erythrocytes in the blood of persons in opposite blood groups and did not cause agglutination in the blood of persons whose blood group was the same as that of the donor. Agglutination of blood of persons in opposite blood groups occurred more rapidly when blood serum of the donor was used than when juice of gastric mucosa was used. Complement fixation occurred in the blood serum of normal persons of a given blood group who received from two to four parenteral injections of juice of gastric mucosa of a donor belonging to a different blood group. The phenomenon occurred when the blood serum of the receiver was treated with the juice of gastric mucosa which was previously used for sensitization. It did not occur when the donor of gastric mucosa and the receiver of its juice were of the same blood groups. The authors therefore conclude that gastric mucosa has specific group properties corresponding to those of blood groups. The authors' article is a preliminary note.

Book Notices

Endocrine Therapy in General Practice. By Elmer L. Sevringhaus, M.D., F.A.C.P., Director, Endocrine and Nutritional Clinics, Gouverneur Hospital, New York. Sixth edition. Cloth. Price, $4. Pp. 264, with 49 illustrations. Year Book Publishers, Inc., 304 S. Dearborn St., Chicago 4, 1948.

This helpful little volume will be appreciated by the general practitioner who is confused and has difficulty with the intricate and complex ramifications of endocrine relationships. As with the preceding editions, it is simply written but contains the essentials necessary to the sound practice of endocrinology. This latest edition has been polished and been treated to eliminate some of the minor ambiguities present in the earlier ones. The reviewer has fault with only two sections of this volume: the scant attention to the psychologic factors in the development and treatment of overweight and the lack of a systematic discussion of the ovarian dysfunctions. In regard to the latter, most physicians would be appreciative if this chapter contained headings of the various ovarian dysfunctions and their specific treatment rather than a more or less generalized discussion of these problems. Otherwise, this book is to be commended for its value to practitioners.

Endotracheal Anesthesia. By Noel A. Gillespie, D.M., B.Ch., M.D., Associate Professor of Anesthesia in the University of Wisconsin, Madison. Second edition. Cloth. Price, $4. Pp. 237, with 57 illustrations. University of Wisconsin Press, 811 State St., Madison 5, Wisconsin, 1948.

Any one who has been fortunate enough to read the first edition of this book (1941) will be pleased to know that in the second edition the author has expanded the book from 187 to 237 pages. He has enlarged certain portions of the text and has corrected any errors that he has discovered or that have been brought to his attention. He fortunately has had a fine response from his readers and has received many constructive suggestions which have been followed. However, he has not departed from his original plan of writing a book which is aimed at increasing the clinical skill of the anesthesiologist without necessarily preparing him for examinations. Well written books devoted to one subject are valuable; however, when a second edition appears, it has all the advantages of containing not only the opinions of the author but those of a great many of his readers. Every anesthesiologist should obtain a copy of this book.

Gynecological and Obstetrical Urology. By Houston S. Everett, A.B., A.M., M.D., Associate Professor of Gynecology, the Johns Hopkins University, Baltimore. Second edition. Cloth. Price, $6. Pp. 539, with 232 illustrations. Williams & Wilkins Co., Mt. Royal & Guilford Aves., Baltimore 2, 1947.

The need for fair and balanced presentation of related specialties is self evident. This applies particularly to conditions which confront the obstetricians, gynecologists and urologists. This second edition contains ample information about the anatomy and physiology of the urinary system. The relationship of this system to the reproductive system receives proper considerations. The illustrations are ample, clear and logical.

More emphasis has been placed on gynecologic complications than on conditions in pregnancy, labor and the early puerperium. In the next edition it is suggested that the present adequate obstetric aspects be expanded to match the gynecologic considerations. This imbalance is natural, inasmuch as Dr. Everett is a gynecologist. The urologist should note the author's understanding of urology and urologic conditions.

The author has brought together problems which the urologist, gynecologist and obstetrician must treat and offers thorough diagnostic and therapeutic procedures. For these reasons alone every urologist who sees obstetric and gynecologic patients should possess or have access to the valuable material in this volume. For the same reasons also this edition is recommended to obstetricians and gynecologists, to general practitioners who do obstetrics and to general surgeons who treat pelvic conditions.

The publishers deserve credit, too, for the quality of paper and style and size of type.

Developing Your Child's Personality. By Gelolo McHugh, Ph.D. Cloth. Price, $2.75. Pp. 234. D. Appleton-Century Co., 35 W. 32d St., New York 1, 1947.

This is a pleasantly written discussion of early training and rearing of children. The emphasis is upon the parent's responsibility for healthy emotional and social growth of the child, as the title indicates. The author starts with "Planning for Parenthood," and the final chapter is "Preparing for the Second Child." The material presented in this book is good and can be profitably read by expectant parents or parents of small children. An easy, chatty style in which the reader is consistently addressed in the second person is generally acceptable, though the reader at times feels that he is being lectured. The author makes of baby rearing something relatively simple, a pleasant experience for parent and child. On the whole, this is a good attitude to adopt in talking with parents. But the author overlooks or ignores, at least in this book, the deeper powerful influences of family relationships as they reflect themselves in character structure and in healthy or unhealthy life attitudes. The following sentence indicates his point of view: "There is really no more mystery about the hampering fears from which children and adults suffer, or about their inability to get along with others, than there is about dislikes for milk or learned unwillingness to try new foods." It is true that there is no mystery about basic human relationships, but the author implies that a simple conditioning, all consciously imposed by the parents, is all that is involved in early child rearing. This approach is adequate for a large number of parents who themselves have been reared in a rather healthy manner and who can carry this experience over into their dealings with their children. For a large number of parents not as well equipped, a more penetrating understanding of the nature of childhood and parental likes and dislikes, fears and hostilities would be required. This book can readily be recommended to parents.

Psychoanalytic Therapy: Principles and Application. By Franz Alexander, M.D., and Thomas Morton French, M.D., [with Staff Members of the Institute for Psychoanalysis, Chicago]. Cloth. Price, $5. Pp. 353, with 1 illustration. The Ronald Press Company, 15 E. 26th St., New York 10, 1946.

Renewed interest in the problems of emotional disturbances and their effects on body changes have made an understanding of basic principles of psychoanalysis a necessity for the modern physician. Drs. Franz Alexander and Thomas M. French with the assistance of the staff of the Chicago Institute of Psychoanalysis have written a compact, readable textbook of the latest developments in the field of dynamic psychiatry. A careful review of 292 patients seen at the institute, many private patients and the broad experiences of Drs. Alexander, French and other staff physicians formed the basis for the book.

Emotional and personality changes were viewed from a broad basis that included not only infantile experiences, but adolescent and adult reactions. Unlike the standard psychoanalysis, the authors did not confine themselves to the problems of the chronic neurotic patients, but included a study of acute neurosis and incipient neurosis. From their observations they were able to develop a better appreciation of the painful reactions to the ego that often occurred in adult life as well as a knowledge of the mechanisms by which adults met such situations. This led to a better understanding of the development of personality and gave meaning to the dynamic approach of certain psychiatrists.

Treatment of emotionally disturbed patients has been developed along the lines of their individual needs. Traditional daily psychiatric interviews, long held by some as essential for the proper understanding of patients, have been questioned. The use of the couch as a means of enabling the patient to express freely whatever enters his mind, called free association, should be followed by a careful, subtle and effective means of emotional reeducation. It was felt that discreet remarks from the analyst may speed up the process and have the patient reorient himself more quickly than by the standard practices of prolonged analysis. In a sense it was individualizing the treatment of patients just as is done in other fields of medicine.

Flexibility in psychoanalysis was essential to meet the varying problems confronting the analysts. Patients who showed favorable response to treatments should have their interviews spaced farther and farther apart to avoid dependence on the analyst. Often judicious scheduling of interviews allowed the patient to translate and incorporate much of what he learned while on the couch into actual life experiences and thus develop his personality so that he could more effectively cope with future interpersonal relations. Treatment should not be considered to continue for a long period of time merely so that all phases of the patient's personality can be explored, but when a satisfactory adjustment of the salient problems has been met in the opinion of the psychiatrist, the patient should be allowed to demonstrate his progress. Psychoanalysts trained in the traditional methods will not agree with the authors; however, the results obtained at the institute indicate that Drs. Alexander and French have more realistically met the needs of many different kinds of emotional disturbances than has been accomplished in the past. Their dynamic approach also makes it possible for more persons with acute, latent or mild neurosis to be benefited by psychiatric treatment.

The second part of the book contains illustrative cases of the various methods of psychoanalytic therapy. Efficacy of short interviews and treatment, value of supportive therapy and emotional reeducation, various methods of using transference, alleviation of rigid standards and narcosynthesis in war neurosis each form individual chapters. One or several patients' histories were given in detail, followed by a short discussion of the important features and in some instances a brief summary of the material presented in the chapter.

In the concluding chapter Dr. Alexander ably presents the development of psychoanalysis from Freud to the present, gradual acceptance of the dynamic concept of personality development and the need of further experimentation to find easier and better methods of treating all emotionally ill persons.

The book should be of help to general practitioners, medical students, psychiatrists, psychologists and social workers. Each staff member is credited with his contribution, and Miss Helen Ross, administrative director of the institute, was responsible for making it a readable interesting handbook of treatment rather than a disorganized compilation of many observations and points of view. The book is printed in easily readable type, well indexed and is recommended to all interested in understanding psychosomatic medicine as well as the larger aspect of improving man's ability to live with man.

Beiträge zur Kenntnis der Blutgerinnung. Von W.K. Rieben, Professor für experimentelle Medizin an der Universität Oregon. Paper. Price, 9 Swiss francs. Pp. 96, with 26 illustrations. [Imported by Grune & Stratton, Inc., 381 4th Ave., New York 16]; Benno Schwabe & Co., Klosterberg 27, Basel, 1947.

This little monograph contains some original contributions of the author to the confusing problems of blood coagulation. First a relatively simple two step method for the determination of prothrombin is described. Although the practical clinical significance of Quick's one step method is acknowledged, the theoretical foundation of the Quick test is severely criticized. After description of the influence of many factors on the determination of the prothrombin time, the effect of amino acids, ascorbic acid, taurin and cystein are particularly mentioned. Dihydroxyphenylalanine was found to inhibit coagulation in vitro and in vivo and is recommended for a clinical trial in thromboembolic disease. The book contains contributions of interest to the investigator in the field of coagulation.

Textbook of the Ear, Nose, and Throat. By Francis L. Lederer, B. Sc., M.D., F.A.C.S., Professor and Head of Department of Otolaryngology, University of Illinois College of Medicine, Chicago, and Abraham R. Hollender, M. Sc., M.D., F.A.C.S. Second edition. Cloth. Price, $7. Pp. 596, with 182 illustrations. F.A. Davis Co., 1914-16 Cherry St., Philadelphia 3, 1947.

This is a textbook designed for medical students; it should be of great value to the general practitioner. Among its finely illustrated pages are to be found practically every condition which might be included in otolaryngology. Because the authors appreciate the limitations of those for whom the book is intended, they adhere to a simple clear style which serves their purpose well. Essential fundamentals are stressed. The first section, consisting of five chapters, deals with general considerations under the general heading: "Introductory"; it is well done. The book is divided into nine sections comprising seventy-two chapters. Deserving of special mention are the previews which serve as a background or basis for the text which follows, and the one hundred and eighty-two illustrations, which are consistently of high quality.

Within its scope this is a comprehensive and complete textbook which has already gained wide usage and favorable recognition. The style, the print, the paper, the general format, all combine to encourage those who may peruse it to utter words of praise and commendation. The authors and their publisher are to be congratulated.

Congenital Malformations: A Study of Parental Characteristics with Special Reference to the Reproductive Process. By Douglas P. Murphy, M.D., F.A.C.S., Assistant Professor of Obstetrics and Gynecology and Research Associate in the Gynecean Hospital Institute of Gynecologic Research, University of Pennsylvania, Philadelphia. Second edition. Cloth. Price, $5. Pp. 127, with illustrations. J.B. Lippincott Co., 227-231 S. 6th St., Philadelphia 5, 1947.

This second edition of this monograph aims to throw additional light on some of the questions which parents of congenitally defective children are likely to ask their doctors. The material for this study represented the families of malformed children who had died. The names were obtained from stillbirth and death certificates in Philadelphia and its environs.

The author concludes that malformations are congenital or environmental in origin. There are only two environmental conditions which lead to malformations, rubella and therapeutic irradiation of the pelvic organs during pregnancy. Rubella early in pregnancy results in a high incidence of malformations of the fetus. Preconceptional rubella probably does no harm to the offspring. In a study of 38 unhealthy children born after postconceptional pelvic irradiation, in 28, or 73.6 per cent, the defect could be definitely attributed to radiation. The majority of them were mentally defective. Although irradiation to the maternal pelvic organs during pregnancy is likely to cause serious damage to the fetus, there need be little fear of damage to the germ plasm and subsequent abnormal fetuses. This conclusion by the author is premature, for much more extensive data will be available in the near future on this subject.

Most of the malformations are genetic in origin. The chance that any couple will have a defective offspring is 1 in 200. The likelihood that a subsequent malformed child will be born to a family which has had a malformed child is increased twenty to twenty-five times. The hazard of malformations increases with the age of the mother, rising progressively year by year after the mother has passed 30, and is three times as great after 40 as after 30. Again, youth is the best safeguard for normal reproduction.

400 Years of a Doctor's Life. Collected and Arranged by George Rosen, M.D., and Beate Caspari-Rosen, M.D. Cloth. Price, $5. Pp. 429. Henry Schuman, 20 E. 70th St., New York 21, 1947.

Among the most inspiring contributions to medical biography is this contribution of collections from some of the best known biographies in medical biographic literature. The authors have divided selections from great numbers of biographies into such headings as early years, school days, the medical student, the doctor marries, the doctor goes to war and reflections on life and death. Interspersed are brief notes as to the individual physicians whose contributions are included. This book can be read with profit by every senior medical student and intern, by every physician who is at all concerned with the philosophy of medicine. Many a graduating class would profit more by the reading of selections from this volume than by the rehashes of medical lore and opinion which are usually accumulated in the form of convocation addresses.

Catalogue of Medical Films. Compiled by The Royal Society of Medicine and The Scientific Film Association. Paper. Price, 7s.6d. Pp. 125. ASLIB (Association of Special Libraries and Information Bureaux), 52 Bloomsbury Street, London, W. C. 1, 1948.

This catalogue consists of two parts, namely: Part I, an alphabetical index of eight hundred titles of motion pictures subdivided by subject groups such as anatomy, dermatology and endocrinology, and a numerical cross reference. Part II contains the names of two hundred abstracted films which appear to be rather complete; however, no evaluation has been made on any of the listed films. In the numerical cross reference section, seventy-four catalogue numbers are included without titles.

In addition to films for the medical profession, motion pictures on such subjects as health, dentistry and veterinary medicine are also included.

Films representing several countries other than Great Britain, such as United States, Germany, Australia, Sweden and Scotland, are listed in this catalogue

The appendix consists of a brief history of the following societies: The Scientific Film Association, organized in 1943 and devoted to the interest of film users, The Royal Society of Medicine and the Association of Special Libraries and Information Bureaus, which acts as a clearing house for specialized information and to help remedy a certain lack of knowledge of sources of information.

The organizations concerned in the preparation of this catalogue are to be commended for publishing this consolidated list of medical motion pictures. However, the publication would be of little practical value to the members of the medical profession in the United States inasmuch as the films would not be readily available for their use.

Mind and Memory Training. By Ernest E. Wood. Reprint of second edition. Cloth. Price, $2.50. Pp. 188, with illustrations. Pitman Publishing Corporation, 2 W. 45th St., New York; Sir Isaac Pitman & Sons, Ltd., Pitman House, 39-41 Parker St., Kingsway, London, W. C. 2, 1945.

This book attempts to set up a natural and spontaneous memory system patterned after the mind processes of persons with good memories. Many of the author's conclusions are based on study and observation of the memory systems of Europe and India.

Four "Roads of Thought" which hold ideas together in the mind are suggested and labeled as the laws of class, parts, quality and proximity. Connecting ideas according to these laws in rational order is held to be the secret of memory training. Concentration, for example, is simply the art of detailed examination of an object in the light of these four laws.

The value of creating clear mental images, the constructive use of imagination, the relation of study and reading to memory training, and methods which may be used to simplify or symbolize abstract or complex ideas are discussed in detail. Ways of developing and utilizing a logical series and expanding ideas are among other processes given considerable attention. Memory tricks and some of the feats of the memory men of India are analyzed and described.

The methods advocated are a departure from commonly accepted procedures. While the book makes interesting reading and certain of the devices may have practical merit, it is difficult to see their value for those whose patterns of thinking and study have been established along rather fixed lines.

Diabetes and The Diabetic in the Community. By Mary E. Tangney, R.N., Diabetic Supervisor, Hartford Hospital, Hartford, Connecticut. Cloth. Price, $2.75. Pp. 259, with 18 illustrations. W. B. Saunders Co., W. Washington Sq., Philadelphia 5, 1947.

Where Miss Mary E. Tangney, R.N., confines herself to advice to patients from the nurse's point of view and to the place which the nurse holds in the field of diabetes she does a good job; the fault with this book is that the authoress takes over too much the function of the physician. She says that "The physician usually orders a small dose of protamine zinc insulin, approximately 20 units, at the first visit, after diagnosis has been established. If the patient is young, 30 units may be ordered; if the patient is elderly, 10 to 16 units." Many physicians do not follow this practice; the layman or nurse who reads this book may say that his physician is not giving the proper treatment. This is a sample of the many controversial questions, such as the type of insulin that is most effective in the treatment of diabetes, the use of alkali in the treatment of coma, the various methods of testing for urine sugar, on which the author reaches definite conclusions. Since physicians are not agreed on these subjects, a nurse should hesitate to decide for the public what is the truth.

In the preface Miss Tangney says that the book is written primarily for the person in a community not accessible to hospitals. Later in her discussion of the coma treatment she states that "when the blood sugar falls to a level of 200 milligrams, glucose may be added to the saline, or carbohydrate may be given orally. Dr. Howard Root does not believe the glucose should be added until the blood sugar has fallen to this level." Dr. S. Soskind and his followers do not agree with this. The instance just mentioned is one of several in the book in which the author takes a stand with doctors of a certain group of thought, opposed to the opinions of another group. The patient is only confused by such statements, and not helped.

Pasteurisation. By Harry Hill, F.R.San.I., A.M.I.S.E., F.S.I.A., Provincial Milk Advisory Officer, Ministry of Agriculture and Fisheries. Second edition. Fabrikoid. Price, 21s. Pp. 296, with 73 illustrations. H.K. Lewis & Co., Ltd., 136 Gower St., London, W.C. 1, 1947.

In a thorough, concise manner the author has presented the essential arguments in a brief supporting " pasteurisation " as a public health safeguard for fluid milk supplies. The need for safeguarding milk consumers against milk-borne infectious diseases is reviewed and the usual criticisms advanced against pasteurization are answered. The essentials of the safe, quality milk supply are set forth as (1) clean milk, (2) licensing of milk pasteurization plants, (3) medical control personnel, (4) routine inspection, and (5) laboratory control. The major part of the text is devoted to a detailed discussion of dairy plant construction, maintenance and operation. The necessity for efficient supervision of milk pasteurization plants by both management and public health officials is emphasized. The various methods of applying the pasteurization process to milk and milk products is discussed in detail. This subject has been treated thoroughly and provides a splendid analysis of the various types of equipment developed for the application of the pasteurization process. The information contained relative to pasteurization processes will be of particular interest to dairymen as well as health authorities. The postpasteurization processes involved in the packaging and distribution of pasteurized milk and milk products as well as the sanitationn of processing equipment are probably of specific interest to dairymen; however, the author stresses the efficiency of these processes in relation to safe milk supplies. The importance of routine inspections and laboratory control is also discussed; in particular, methods of making inspections and the various chemical and bacteriologic devices available for use by milk-control agencies. Throughout the entire book, efficiency is cited as the method of dissipating suspicion of the pasteurization process and improving its commercial application. The responsibility for efficient application rests with the progressive operators of plants for milk pasteurization and adequate legislative control.

A Textbook of Surgery for Nurses. By Edward S. Stafford, B.A., M.D., F.A.C.S., Assistant Professor of Surgery, The Johns Hopkins University, Baltimore, and Doris Diller, B.A., R.N. Instructor and Supervisor, Surgical Nursing, The Johns Hopkins Hospital School of Nursing, Baltimore. With a foreword by Anna D. Wolf, M.A., R.N., Director of the School of Nursing and Nursing Service, The Johns Hopkins Hospital. Cloth. Price, $3.25. Pp. 577, with 170 illustrations. W. B. Saunders Co., W. Washington Sq., Philadelphia 5, 1947.

This book is written by a noted surgeon and teacher of surgery, in collaboration with an experienced surgical supervisor and teacher of surgical nursing. Believing that the more the nurse knows about surgery, the aims of the surgeon and what has been done in the operating room, the better will she be able to care for the surgical patient, the authors' chief purpose in writing the book is to furnish this background of surgical information. This they accomplish unusually well. The material is up to date and well presented. It is arranged in fourteen units which adequately cover the field of general surgery and all the surgical specialties (several chapters are contributed by colleagues). The specific nursing care of each condition is described carefully, so that the nurse is fully aware of her exact duties in every situation.

The book is written in clear, simple language. It is concise and singularly free from nonessentials and unnecessary technicalities.

Outstanding are the numerous pen and ink sketches made especially for this work by members of the Art Department of the Johns Hopkins Medical School. These excellent and accurate illustrations greatly illuminate the text and thus enhance its teaching value.

The book is recommended unhesitatingly for the purpose for which it is intended.

The 1947 Year Book of Obstetrics and Gynecology. Edited by J.P. Greenhill, B.S., M.D., F.A.C.S., Professor of Gynecology, Cook County Graduate School of Medicine, Chicago. Fabrikoid. Priçe, $3.75. Pp. 590, with 117 illustrations. Year Book Publishers, 304 S. Dearborn St., Chicago 4, 1948.

Here are the same excellent qualities that readers of this year book have come to appreciate in the past score of years or more. The articles reviewed are those which have worth while contributions; when necessary, controversial reports and unacceptable conclusions are pointed out by the able editor, whose comments and addenda from his rich personal experience, broad view and knowledge of the literature offer valuable and constructive critiques that help to clarify the moot questions. As in former years, the scope of the articles reviewed includes practically all, if not all, of the important papers published in 1947 dealing with obstetric and gynecologic problems. The Year Book of Obstetrics and Gynecology has a welcome place in the library of obstetricians and gynecologists, as well as the general practitioner. It fulfils a definite need for all these groups of physicians who may otherwise have missed many of the worth while publications. It brings them up to date with the literature at the beginning of each year

Chirurgie fonctionnelle gynécologique: Indications opératoires, techniques et considérations pratiques en rapport avec les acquisitions endocrinologiques. Par R. Bourg, chef du service universitaire de gynécologie à l'Hôpital Brugmann, Bruxelles. Préface de E. Douay, president de la Société française de gynécologie, Paris. Paper. Price, 750 francs. Pp. 268, with 137 illustrations. Masson & Cie, 120 Boulevard Saint-Germain, Paris 6^{e}; Editions Desoer, 21 Rue Sainte-Véronique, Liége, 1947.

This small, paper-covered volume presents the indications, technics and practical considerations for surgical procedures to correct malfunction of the pelvic organs. It is difficult to confine the discussion to this phase of gynecology because disturbed function of organs may be the result of disease as well as perverted function.

The author describes the accepted methods of evaluating ovarian function, such as biopsy of the endometrium, body basal temperature and vaginal smears. He recommends that endometrial biopsy be carried out forty-eight hours prior to menstruation rather than at the onset of bleeding. However, many of the surgical procedures on the ovary are not used in this country. We rarely puncture or resect follicle cysts. Ovarian transplantations are not done. He does emphasize the importance of conservation of ovarian function in young women.

In the treatment of sterility, he likewise suggests many operative procedures which have long been obsolete. The numerous operations on the cervix such as Bier's leech, Pozzi operation, Irabarne's tube, resections and amputations have long fallen into discard. However, operations for the establishment of tubal patency should be done more often since the introduction of newer surgical procedures.

There are many illustrations which help to clarify the text. The book is well worth reading by all interested in gynecology, for it presents a wholesome point of view in the management of many gynecologic conditions.

A Reference Manual on Modern Electric Household Refrigeration and Home Freezing. Reference Handbook No. 3, Westinghouse Educational Series. New edition. Paper. Pp. 28, with illustrations. Westinghouse Electric Corporation, Home Economics Institute, Mansfield, Ohio, 1946.

This is a useful booklet of twenty-nine pages which gives basic information with reference to home refrigeration in nontechnical terms. The refrigerator, the freezer and home methods of quick freezing are discussed. The booklet should be useful to those who have household problems in this field.

A History of the Worcester Royal Infirmary. By William Henry McMenemey, M.A. Cloth. Price, 21s Pp. 356, with illustrations. Press Alliances, Ltd., Bouverie House, Fleet St., London, E.C.4, 1947.

This book prepared for the bicentenary of the Worcester Royal Infirmary commemorates the founding of the hospital in 1746. It is an absorbing story of an institution which, founded in the spirit of charity, has rendered unselfish service to the people of its community for two hundred years under the traditional system of voluntary support. Authoritative and rich in illustrations, the book recounts the early days of the hospital, its gradual growth and development and eventual expansion into the modern hospital service which characterizes the present era. Interspersed with the hospital events which flow as the central theme is a wealth of material on administrative problems, the changing pattern of nursing service and the growth of medical practice, ethical relationships, early differentiation in medicine and surgery and the formation in 1732 of the Provincial Medical and Surgical Association, which in turn became the British Medical Association. Glimpses of contemporary social life are evident in many of the chapters, including the special accounts of physicians and other persons prominent in the history of the institution. This book with its vast amount of information, skilfully presented, is a welcome addition to the literature of the hospital field

The Occasion Fleeting. By Hugh Barber. Fabrikoid. Price, 15s. Pp. 199. H. K. Lewis & Co., Ltd , 136 Gower St., London, W. C. 1, 1947.

Here is a collection of essays most of them previously published in the Guy's Hospital Gazette and in the Practitioner. The author's style is pleasant and of the type in which many physicians indulge when sitting around a fireplace for a gossipy evening. Some of the British idioms and diction may be slightly confusing.

A Doctor in the House. By Henry Pleasants Jr., M.D., F.A.C.P. Cloth. Price, $3. Pp. 286. J. B. Lippincott Co., 227 S. 6th St., Philadelphia 5, 1947.

The author of this interesting book of medical reminiscences has a style well adapted to a public audience. The book is essentially an autobiography of its author, who has been for some years a general practitioner. His career brought him into contact with many leaders of medicine, particularly in the East. There are accounts of medical service in World War I, of the relationship of doctors to patients and medical bills, and some special discussions of child care and allergy. His chapter dwelling on the physician as a writer will be an inspiration to every young physician with similar ambitions. Unfortunately Dr. Pleasants believes that young men can be encouraged to practice in rural areas by educating a poorer quality of physicians who will enter medical school directly from the high school. Actually he believes that the way to get more physicians into the rural areas is to make medical education less difficult, but most leaders are convinced that a good country doctor ought to be even better than the general practitioner from the city.

Disease Transmitted from Animals to Man. By Thomas G. Hull, Ph.D., Director, the Scientific Exhibit, American Medical Association. Third edition. Cloth. Price, $10.50. Pp. 571, with 75 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill., 1947.

Tremendous progress has been made in the control of many of the diseases that formerly passed from animals to man. Some, such as bovine tuberculosis and glanders, have been practically eliminated as menaces in the United States. However, diseases undergo evolution exactly as do other factors in human life. Now new chapters have become necessary on such subjects as tsutsugamushi disease, Q fever, jungle yellow fever and Haverhill fever. Moreover, what is one of the greatest outbreaks of foot and mouth disease ever to appear is now menacing cattle in Mexico and the United States It is well to have an authoritative work of this kind.

Essentials of Prescription Writing. By Cary Eggleston, M.D., Associate Professor of Clinical Medicine, Cornell University Medical College, New York City. Eighth edition. Cloth. Price, $2. Pp. 155. W.B. Saunders Co , W. Washington Sq., Philadelphia 5, 1947.

The fundamentals of prescription writing would seem to preclude radical change. But striking changes have taken place, as seen in the growing tendency to use the metric system in the substitution of English titles for the Latin by the Pharmacopoeia, the National Formulary and in prescriptions, in the dropping of the old galenicals and their replacement by chemical drugs and active principles, in the tendency to prescribe potent drugs by themselves rather than in a shotgun mixture and in the extensive employment of hypodermic and intravenous administration. We must still write prescriptions, but the finished prescription differs from that of thirty years ago.

While the author has devoted much space, as in previous editions, to the prescription in Latin, he has added a whole chapter on The Modern Prescription, and out of the old has graduated into the new as a matter of evolution. He accepts "about 5 cc." as the equivalent of a teaspoonful, though this is a variable quantity in household teaspoons. He does not urge the use of medicine glasses or the modern plastic teaspoons, which accept 4 cc. as one teaspoon and are to be had cheaply. His descriptions of the Pharmacopoeia and the National Formulary require clarification. Yet this little book, which covers the subject fully but briefly, may be just what is needed to ease the doctor's mind when he issues an order on the pharmacist in the form of a prescription.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

TRICHOMONAS VAGINALIS

To the Editor:—In November 1944 a white woman, aged 25, called her physician for uncontrollable vaginal bleeding. A diagnosis of miscarriage was made and the patient was treated accordingly by nonsurgical methods. Bleeding persisted until February 1945, when I was called to see the patient. I did a dilatation and curettage, the report reading "premenstrual stage." Testosterone was given over a period of time without success. Bleeding continued despite my efforts, and as a last resort a supravaginal hysterectomy was done; the ovaries and tubes were left intact. The pathology report stated that the uterus was twice its normal size and that there was a chronic metritis.

She did well until a month ago, when she came in with the story of having noticed blood spots on the sheet on arising. She noticed this about four or five times even without intercourse. She also was aware of a profuse vaginal discharge for the past year, and recently intercourse had become extremely painful. Other than that, she had been feeling better than in years. The discharge proved to be due to a Trichomonas infection. The cervix was normal in size, shape and position; there were no erosions or polyps. A pelvic examination revealed no masses bimanually. The consultant, after his examination, was convinced this was all due to the Trichomonas infection.

I am interested to know whether this infection will give bleeding and whether another dilatation and curettage is indicated? Would a large ovarian cyst, if one was present, cause bleeding in this case?

Hilda Lang Berenson, M.D., Lynn, Mass.

ANSWER.—The data offer much room for speculation. Did the young woman actually have a spontaneous abortion? A Friedman test at the time might have given the answer, as might also the vaginal smear method of Papanicolaou. The findings of a premenstrual stage in the currettings or secretory stage are also of interest because patients rarely bleed from this type of endometrium, if normal. The finding of a chronic metritis is rather unusual and one should be on the lookout for such things as stem pessaries, pedunculated submucus fibroids, degenerating malignant growths and especially tuberculosis or possibly endometriosis of the uterus or adenomyosis.

Trichomonas vaginitis can be extremely irritating and either through intercourse or scratching produce abrasions which bleed. Also, as sometimes happens following hysterectomy, the circulation to the ovary is disturbed, leading to atrophy of these organs and a senile vaginitis which frequently bleeds with the trauma of intercourse.

Bleeding without trauma, however, is of more serious significance. Is the author sure that all of the uterus was removed, or was some endometrium left? If the uterus was removed, a curettage could not be done, but the cervical stump should be carefully investigated for cancer, particularly endocervical. Endometriosis not infrequently is seen in the cervix or vaginal wall, and these areas may menstruate if there is ovarian function. Tubercular ulceration of the cervix is rare.

Certainly a Friedman test should be done to rule out chorioepitheliomatous metastases. Vaginal smears after the method of Papanicolaou are useful in the diagnosis of cancer.

A large ovarian cyst should not cause this type of bleeding unless it was malignant and by direct extension the tumor grew through the vaginal wall.

ATHLETIC SUPPORT

To the Editor:—Does continual wearing of an athletic support result in premature enlargement of the prostate or in overstimulation of that gland?

M.D., Connecticut.

ANSWER.—No.

ARTIFICIAL EAR DRUM

To the Editor:—In many patients with a total loss of one or both ear drums the hearing can be remarkably improved by an artificial ear drum. The patients learn quickly to insert the ear drum in the proper place so that they are independent of the otologist. I have a number of patients, accustomed to an artificial ear drum, who prefer not to be without it. Can you inform me where I can obtain artificial ear drums?

Joseph Berberich, M.D., New York.

ANSWER—The American Optical Company, 8 South Wabash Avenue, Chicago, Illinois, carries a type of artificial ear drum which the patient may insert himself in suitable cases in which the drum membrane is absent and there is no active suppuration.

PROTEINURIA

To the Editor:—As an armed forces recruit medical examiner I have recently encountered an unusual increase in the number of cases of albuminuria coming to my attention. A few appear to be due to chronic nephritis, acute or chronic pyelitis, stone, abscessed teeth or recent acute illness. Irritation from drugs or poisons has appeared unlikely in all cases. It is those cases in which it is not possible to make a presumptive diagnosis that have me perplexed. Although I have been at my present duty station for fifteen months it is only in recent months (September and October, 1947) that the number of cases of albuminuria has apparently increased. During the months of June and July, 1946, physical rejections from all causes amounted to approximately 10 per cent. The applicants appeared to be of high caliber and were principally young men who had just finished high school. Rejections for albuminuria amounted to about 1 per cent. At present albuminuria causes the rejection of almost 20 per cent of applicants. However, the applicants at present are on the whole of a lower caliber. Albuminuria if constantly or intermittently present is cause for rejection, according to regulations, even if the origin *cannot be determined* (orthostatic albuminuria would be acceptable if it were possible for the medical officer to satisfy himself as to the diagnosis). It has been the practice of myself and co-workers to use Robert's reagent and then recheck all positive urinalyses by means of the heat and acetic acid test. We abide by the letter of the regulations and accordingly reject all applicants who show even traces of albumin on repeated tests, even if microscopic examination, history and physical results of examination are negative. It is not possible to give equal weight to a *negative history from an applicant and that from a patient in* private practice. The applicant frequently attempts to conceal important data for fear of rejection.

1. Is our present policy of rejecting all applicants who show persistent albuminuria, even in trace amounts and with negative microscopic examination, history, and physical examination, too severe?

2. What percentage of an average group of adolescents might be expected to show orthostatic albuminuria?

3. Have such factors as food, spices, chemical content of water or soil been *shown to cause albuminuria?*

4. Would fatigue caused by a hundred mile train ride be a likely cause of albuminuria, and how long might it be expected to persist?

5. What is the present attitude of insurance companies toward young adults with albuminuria, normal microscopic appearance of the sediment and a negative history and physical examination?

E. J. Sullivan Jr., M.D., Baltimore.

ANSWER.—The problem of proteinuria in applicants for the armed forces demands serious attention because of the high incidence in the second decade, the importance of excluding the extremely low percentage of organic renal disease and the influence of extraneous factors in producing transient proteinuria in a rather high percentage of recruits, provided frequent urinalyses are performed. A number of excellent reports on this subject have been published in recent years. While physical fitness may be involved in those cases of proteinuria associated with malnutrition, poor muscle tone, defective posture or vasomotor instability, this is only one aspect of the problem. Basically, functional proteinuria is nearly always the result of renal vasoconstriction, whether of reflex or humoral chemical origin.

1. If persistent albuminuria is not associated with abnormal urinary sediment in a highly concentrated acid urine or with evidence of origin from prostate or seminal vesicles, postural or lordotic tests should be carried out carefully before rejecting the applicant. What is meant by "persistent"? The urine should be examined several times daily for several days under the precise conditions outlined in the references. Otherwise, many applicants will be turned down unnecessarily because of proteinuria due to exercise or emotional stimulation.

2. The percentage of adolescents with orthostatic albuminuria varies with age, the procedure, the frequency of testing, the season and other factors. It is highest at 16 years of age, about 5 per cent, and drops sharply with each succeeding year to less than 1 per cent at age 20. The incidence in July and August may be twice that in other months, presumably because of more concentrated urines.

3. The consumption of a considerable amount of raw egg white or a huge quantity of irritant spices may cause transient proteinuria in a susceptible subject. Chemical factors in water or soil are of no import in this regard.

A long train ride could well produce orthostatic proteinuria but this should disappear with recumbency.

5. The large insurance companies have learned from experience that there is no abnormal mortality in subjects with intermittent proteinuria proved to be orthostatic. Suspicion is aroused if the proteinuria exceeds 50 to 75 mg. per hundred cubic centimeters. An intravenous pyelogram may be requested to exclude urologic disease. On satisfactory evidence of the functional nature of the proteinuria in an applicant under 30 years of age, insurance will be granted without rating up

PAPAYA

To the Editor:—Is there a vegetable pepsin in papaya? If so, is there more in the ripe or green papaya? Is there any vegetable pepsin in the seed of the papaya? Is the papaya of any value in tenderizing meat?

M.D., Texas.

Answer.—The green fruit of papaya, Carica Papaya, is the chief source of the proteinase known as papain, which is a powerful proteolytic enzyme and is widely used for "tenderizing" meat. Crude commercial papain is prepared from dried latex collected from green fruits of the papaya plant. The proteinase activity decreases with the ripening of the fruit. The ripe fruit is eminently edible. Other parts of the plant are known to contain some papain.

CONGESTIVE HEART FAILURE

To the Editor:—I have seen patients in failure of the right side of the heart with clinical signs of nephritis and widespread rales in the lungs. Is cardiac failure on a rheumatic basis associated with the nephritis or are the thoracic rales those of pneumonia or failure of the left side of the heart? How can one differentiate between congestive failure on the basis of an associated rheumatic fever or a pure nephritis, granting that the urine shows albumin, red blood cells and casts?

M.D, New York.

Answer.—Two possibilities exist to explain the foregoing observations First, congestive heart failure complicating rheumatic, hypertensive, coronary or other type of heart disease may produce evidence of such congestion both in the lungs (with basal rales) and in the systemic circulation with engorgement of the neck veins, liver and kidneys. Albuminuria with sediment is common in such conditions, and if there is a tendency to hypertension there is likely to be an increase thereof during the congestive failure. Most of the patients who were labeled as having cardiorenal disease in the old days actually had hypertensive heart disease with congestive failure.

The other possibility is that acute nephritis, especially of the hemorrhagic variety, may be associated with or lead to cardiac involvement and congestive failure, including edema of the lungs, which subsides after the acute renal process has cleared. Thus, it is important to note the antecedents in any case and to gage with considerable accuracy the severity of the actual renal involvement. If a patient without previous heart disease shows a picture such as that mentioned, one should look for nephritis with pulmonary edema. If, on the other hand, considerable chronic heart disease is known to have existed, then congestive failure with or without added nephritis should be suspected The history and signs of structural heart disease and detailed renal studies as a rule afford the clues. Acute rheumatism of itself seldom produces this picture. Of course, there may be coincident diseases such as pneumonia and cardiac or renal disease.

RUBBING ALCOHOL

To the Editor:—I would like information or sources of information on the toxicity of rubbing alcohol. One preparation is ethyl alcohol with some flavoring substance added, and another preparation is isopropyl alcohol. Death occurred recently in a man aged 35, who was under observations for three days with weakness of the muscles of his arms and shoulders, vomiting, temperature ranging from 100 to 100 2 F. and pronounced mental confusion. Spinal puncture was not performed because he had had an extensive fusion operation for a compression fracture of his spine ten years ago. He died suddenly and unexpectedly from respiratory failure. He was a silent alcoholic of several years' duration and supposedly had taken some rubbing alcohol (unknown amount) five days before his death. In trying to arrive at a diagnosis poliomyelitis and acute myelitis were considered, but his mental confusion did not seem to fit in with conditions in those diseases.

M.D., North Dakota.

Answer.—There is wide variation in the composition of "rubbing alcohols" used in different institutions. Usually they consist primarily of denatured ethyl alcohol or of isopropyl alcohol in 50 to 70 per cent solution. Denatured ethyl alcohol contains substances which make it unsuitable for consumption—substances which give it a disagreeable smell or taste, or which produce physiologic effects such as vomiting in order to interfere with absorption. An official "special denatured alcohol formula 23 H" contains acetone, methyl isobutyl ketone and sucrose octa-acetate. "Formula 23 G" contains methyl propyl ketone and methyl isobutyl ketone in addition to sucrose octa-acetate. Each formula may also contain various odorous or colored compounds such as methyl salicylate (wintergreen oil) or certified green dye. These substances are not present in amounts large enough to have appreciable toxic effect, especially since denatured alcohol is disagreeable to take and is apt to be vomited if ingested in quantity.

A sufficient quantity of denatured ethyl alcohol taken by a habitual drinker might well cause vomiting, mental confusion and a moderate elevation of temperature, but that episode alone would hardly explain the reported muscular weakness of arms and shoulders or sudden death after five days.

What little is known about the toxicity for man of isopropyl alcohol when taken by mouth has been summarized by W. F. von Oettingen (The Aliphatic Alcohols: Their Toxicity and Potential Dangers in Relation to Their Chemical Constitution and Their Fate in Metabolism, Public Health Service Bulletin 281, Federal Security Agency, United States Public Health Service, 1943, pp. 121-122). Dizziness, muscular and nervous disturbances and headaches have been reported; also bradycardia and lowering of the blood pressure. Ingested isopropyl alcohol becomes concentrated in certain organs, particularly in the brain, heart muscle and kidneys. Pathologically, moderate reversible fatty infiltration may be found in these organs. Large doses of isopropyl alcohol in animals cause ataxia and narcosis; paralysis and dyspnea may precede death. The minimal fatal dose for rabbits and mice is 6.0 to 7.6 cc. per kilogram of body weight. Morris and Lightbody (The Toxicity of Isopropyl Alcohol, *J. Indust. Hyg. & Toxicol.* **20**:428, 1938) believe that on account of its slow elimination isopropyl alcohol may have cumulative effects, which may be due either to the alcohol itself or to its oxidation product, acetone.

Conceivably, ingestion of a sufficient quantity of isopropyl alcohol could have caused the symptoms listed in the query, but without additional evidence it cannot be stated definitely that this patient's neurologic symptoms and death were due primarily to ingestion of "rubbing alcohol."

PRESBYOPIA

To the Editor.—Has evidence been presented to indicate that the age at which senile presbyopia develops is dependent on hormonal control? Is the early or late development of senile presbyopia a feature of any clearly demarcated endocrine disorder? Cataract is a feature of certain of the syndromes related to progeria; do patients with progeria but without cataract show senile presbyopia?

William Q. Wolfson, M.D., Chicago.

Answer.—Presbyopia is not a condition which comes on with old age, as its name implies. The eye at birth is imperfect. The ciliary muscle, which is the muscle of accommodation, is not yet ready to function. Development goes on for several years. At the age of 8 to 10 years accommodation is fully developed and reaches its maximum.

But accommodation (increase in refractive power) depends not only on the ciliary muscle and its nerve connections but on the capability of the crystalline lens to respond to the muscular action. It responds by becoming more convex not only on its surface but in its inner layers. This is possible only because of the plasticity of the crystalline lens. For a large accommodation, such as 12 D. or more, which is possible in the teens, the changes in the form of the lens are considerable.

As the child grows older the lens loses water and becomes less soft and plastic—in short, it undergoes sclerosis. This does not require any special hormone. If factors such as diet, vitamins and hormones should be found to affect the rate of progress of presbyopia, perhaps retarding it, there is no question but that the inexorable progress of presbyopia would go on—merely being delayed a few months. It is affected, of course, by the general health and metabolism of the person and by local disturbances of nutrition. Some of these result in loss of transparency and are called cataract. The outstanding fact is that the progress of sclerosis from say 8 to 10 years of age till death is steady and remarkably uniform in different persons. Probably there is no part of the body which ages so uniformly as the crystalline lens. Many (including some ophthalmologists) have tried to escape this steady progress by means of exercises and other treatment, but it is inexorable.

Presbyopia does, however, differ a little in different persons. In long-lived families the advance is a little slower, so that some persons at the age of 50 have as much accommodation—as little presbyopia—as others who are 3 to 5 years younger. It is well known that age cannot be measured in years alone. In persons with some myopia it may appear that the advance is slower. It is true that such patients can read at an older age than others, but it is not because their accommodation is of greater amplitude; it is because of their myopia, which may be due to a swelling of the lens either as it takes up more water, swells and becomes more convex or as it changes its refractive index. This accounts for the so-called second sight. Patients who were dependent on glasses to read find themselves again able to read without glasses. This is not due to any recovery of accommodation or avoidance or presbyopia It is due to the onset of cataract, which in many cases is associated with changes in the refractive power of the lens which cause myopia. These patients have better near vision but cannot see as well as before at a distance.

DUYPUYTREN'S CONTRACTURE

To the Editor:—What is the cause of and treatment for Dupuytren's contracture? My patient, a young woman, seems to have tenosynovitis involving the tendons to the middle finger of both hands. These (tendons) are prominent when the fingers are extended and painful enough at times (especially in the early morning) to interfere with rest. There has been no trauma and nothing about her work (housewife) that explains the condition.

Robert E. Cloud, M.D., Birmingham, Ala.

ANSWER.—The causative factors in the production of Dupuytren's contracture include trauma, infection and metabolic disturbances. Trauma might be acute and severe or (more important) multiple and minimal in character. Treatment of Dupuytren's contracture usually means operation.

The tenosynovitis of the palmar tendons to the middle finger of both hands brings up the subject of fibrositis. Unfortunately, the ubiquitous fibrous tissue is poorly understood and its basic disorders inadequately known. Here again the same causative factors come into focus. It is inaccurate to say that "no trauma and nothing about her housework explains the condition." The daily acts in the home constitute *multiple minimal trauma*. A few of these acts are: turning door knobs, using the broom or vacuum cleaner, carving meat, slicing bread and lifting heavy household articles. Occasionally the person with Dupuytren's contracture has a similar lesion of a foot.

FLUORINE IN DENTAL CARIES

To the Editor:—Some of my patients have asked me about the advisability of using fluorine compounds (1) by tablet, (2) in drinking water or (3) in tooth powder. In communities in which the water supply is not fluorinated, is it advisable to add a fluorine compound to the water used in the household for drinking or cooking purposes? What compound do you suggest and in what dosage? Is the addition of such a compound to dental indicated? If so, what and how much is recommended?

M.D., New Jersey.

ANSWER.—In communities in which the water supply is not fluorinated it would not seem advisable to add fluorine compounds to the water used in the household for drinking and cooking. In the cities in which the water is being fluorinated, the concentration is under professional supervision and is not permitted to exceed the optimal level. At Grand Rapids, Mich., for instance, chemical analyses are made daily.

In respect to the use of fluorine compounds in (1) tablets and (2) tooth powder, attention is called to a recent editorial (The Role of Fluorine in Dental Caries: I. Synthetic Fluoride Tablets and Bone Meal Preparations, J. Am. Dent. A. 34:345 [March 1] 1947), which says in part: "Until more convincing data are presented, therefore, the use of fluorides in dentifrices, mouth washes, tablets and lozenges cannot be recommended."

MELENA

To the Editor:—What is the chemistry involved in the production of melena? Can bleeding from the cecum produce melena?

M.D., Illinois.

ANSWER.—The chemical factors involved in the production of melena still await final clarification. Such change is usually attributed to the action of the gastric juice on blood pigment. However, factors other than such a mechanism undoubtedly also play a role, because melena has been observed with variable frequency in traumatic, ulcerative and neoplastic lesions from the level of the upper part of the jejunum downward to the ileum. Benign tumors of the small bowel and hemorrhage from an ulcer in Meckel's diverticulem are good examples of this. Probably contributing, in whole or in large part, to the blackness of the stools are such hemoglobin derivatives in the intestinal tract as *protoporphyrins and deuteroporphyrins*. In Watson's opinion there is no concrete evidence that the coproporphyrins have a similar origin. The former give a positive reaction test with guaiacum or benzidine.

Carcinoma of the cecum can produce melena on rare occasions. As a rule the amount of bleeding is too small to discolor the feces. Factors concerned with the rate and amount of blood lost and the state of intestinal motility must be taken into account. For example, a sudden hemorrhage of 1,000 cc. or more of blood from the stomach or duodenum may cause red feces containing fresh blood.

NECROPSY FOLLOWING INCINERATION

To the Editor: Please send any possible information on the points which follow: (1) Postmortem reports on loss of blood from vessels when both upper and lower extremities are burned off to torso level (also dealing with the possibility that death had occurred previous to the fire). (2) How long after death would blood or blood clots be expected to remain in the superior or vena cava? (3) Would absence of blood in the ascending vena cava while present in the abdominal aorta be of significance?

M.D., Texas.

ANSWER.—Blood does not ordinarily escape from a body, either living or dead, as the result of the destruction of tissue by heat. Heat sufficient to destroy tissue converts the blood in the region of burning into a firm coagulum.

If the collapsed great veins of an extensively burned body are observed to contain so little coagulated blood as to suggest antemortem exsanguination, the next step should be to determine whether or not death had occurred previous to the fire. If a person dies during and because of a conflagration, *the air passages are usually observed* to contain an excessive amount of soot-laden mucus. Absence of evidence that smoke had been inhaled would suggest that the person was probably dead before or soon after the fire started. The carbon monoxide content of the blood is another indication of the time of death in relation to the fire. The absence of carbon monoxide (over 5 per cent saturation) in the fluid blood of a burned body indicates that death occurred before much smoke or other gaseous combustion products had been breathed.

The length of time that recognizable blood or blood clots remain in the superior and ascending vena cava of a badly burned person will vary according to the intensity of the thermal exposure and to the duration of the postmortem interval. If the blood has been thoroughly cooked, it will remain as a firm coagulum for many days. It is possible, however, for the heat to be sufficiently intense to destroy the extremities but of insufficient duration to coagulate the blood in the superior and inferior vena cava. In such an event most of the blood contained in these vessels remains fluid. Early postmortem diffusion of the hemolyzed blood through walls of the vessels into the surrounding desiccated tissues may lead to vascular collapse and apparent loss of blood.

The "absence of blood in the ascending vena cava while present in the abdominal aorta" may be due to the fact that postmortem diffusion of hemolyzed blood occurs more rapidly through the walls of veins than it does through the thicker walls of arteries.

DRIBBLING OF URINE

To the Editor:—Please inform me whether there is any reliable treatment for dribbling of urine in a girl 7 years old, without apparent anatomic anomalies.

Adalbert Miskowiec, M.D., Santa Fe, N. M.

ANSWER.—Any reliable treatment for dribbling of urine in a 7 year old child without apparent anatomic anomalies should be preceded by careful examination and exclusion of bladder or urethral defects. This should be accompanied with a laboratory urinary examination as well as examination of the stool. In this way the following causes for the dribbling may be ruled out: pyuria, diabetes mellitus, diabetes insipidus, pinworms, urethritis and highly acid urine. Roentgenographic examination should be made to rule out spina bifida and foreign body or calculus in the bladder.

If no organic causes are observed, minor psychiatric difficulties, such as neuropathic or personality disorders, should be investigated.

The following drugs may be recommended when no organic cause has been found: tincture of belladonna, sedatives and testosterone propionate, in appropriate doses. Finally, the following nonspecific therapy has been advocated:

1. Instigation of bladder control by training the child to start and stop urinating at command; thus, "Start! Stop! Start!" may be helpful
2. General gymnastics to benefit the health of the child, especially exercises calculated to stimulate normal and uniform circulation are beneficial. Slow bending and stretching, trunk exercises and respiratory exercises are advisable.
3. Sometimes a two day rest cure is given, requiring that the child have his breakfast in bed and remain in bed until his lunch time. Such a plan may be pursued two days each week, at the beginning and the end of the week.

HELIUM IN PNEUMOTHORAX

To the Editor:—Is helium being generally used in pneumothorax? How much slower is its rate of absorption than oxygen? Is the gas used alone, or is it mixed with oxygen and, if so, in what proportion? Where can helium be obtained commercially?

I B. Oldham Jr., M.D., Muskogee, Okla.

ANSWER.—Helium is not being used generally in pneumothorax. It was advocated in a preliminary report by Lieutenant Commander E. Ricen, Medical Corps, United States Navy (U. S. Nav. Med. Bull 40:853-855, 1942) on the premise of prolonging the time interval between air injections into the pleural and peritoneal cavities for collapse in pulmonary tuberculosis. The speed with which gases disappear from body cavities is proportionate to their stability coefficients, diffusion speed and chemical affinities for substances dissolved in the blood. Helium, because of its low solubility coefficient in water and in oil, compared with the coefficients for nitrogen is recommended as a substitute for air, according to this report. Behnke and Yarbrough (U. S. Nav. Med. Bull. 36:542-558, 1938) observed that the solubility coefficients for helium in water and in oil compared with nitrogen is in the ratio of 2 to 3 for water and 1 to 4.5 for oil. Oxygen, a component of air, is absorbed much more rapidly than either of the inert gases, helium or nitrogen. Helium, being an inert element, does not enter into chemical combination with blood substances. Ricen selected peritoneal absorption speed because it offered certain advantages over the pleural cavity for conducting his investigation, since gas collects under the diaphragmatic leaves and is readily visualized by fluoroscope and the results are reasonably accurate. A series of cases of pulmonary tuberculosis with previous phrenic nerve paralysis, supplemented by pneumoperitoneum, was selected for study. All the patients had been receiving weekly injections of 1,000 cc. of air into the peritoneal cavity. In all instances a longer period of time was required for the disappearance of 1,000 cc. of helium from the peritoneal cavity than of an equal amount of air. Four to six days longer were required for the complete disappearance of 1,000 cc. of helium from the peritoneal cavity than for disappearance of an equal quantity of air. Helium was well tolerated by the peritoneal cavity. Apparently helium is used alone; no mention of mixing with oxygen is made. Helium, about 98 per cent pure, can be obtained commercially from surgical supply houses in cylinders. The price is about $3.60 for a size D cylinder. It is used with anesthetic gases.

ENURESIS

To the Editor:—What is the present status of chorionic gonadotropic preparations in treatment of enuresis? The mother of a child has brought to my attention some favorable comments by one of the medical columnists in daily papers concerning use of this preparation. I am unable to find any confirmatory reports, and it appears to me that the potentialities for harm are too great to justify use of these preparations without good cause.

John M. Higgins, M.D. Sayre, Pa.

ANSWER.—The use of chorionic gonadotropic preparations for enuresis has been generally discontinued and should be completely abandoned. Its earlier use was based on a mistaken interpretation of the fact that many girls discontinue bed wetting with the onset of the menses or after the menses are well established. This was thought to indicate a sudden development of a previously weak or undeveloped urinary tract under the stimulus of increased hormones related to the establishment of the menstrual function. For many years this mistaken idea prevented the realization that enuresis ceases with the profound psychic change that comes to every girl at that time: "I'm a woman now and must put away childish things."

After careful examination has failed to reveal any defect or infection in the urinary tract, the treatment of enuresis must be reeducation of the parents as well as the child, rather than the use of any drug, hormone, change in diet or fluid intake or any surgical instrument. Any surgical or medical treatment that is unpleasant, such as repeated injections, may cause an intelligent child to substitute some other infantile behavior for enuresis. When such a substitution is made, enuresis ceases, and the last method of treatment used gets unearned credit, while the child is left without any advance in emotional growth and development and the parents gain nothing that will help them assist their child to become an adult emotionally—a reasonable human being.

STELLECTOMY

To the Editor:—What is the accepted opinion today on stellectomy (surgical removal of the stellate ganglion) for angina pectoris? Have you available the names of the surgeons in Chicago most actively engaged in the use of this method?

H. D. Coles, M.D., Chicago.

ANSWER.—Sympathectomy for angina pectoris has limited usefulness in relieving intractable pain in patients whose *myocardial* reserve permits a two stage retropleural operation. Stellectomy alone has been observed to be insufficient for this purpose, and it is necessary to remove the ganglionated chain from below the fifth dorsal segment to above the second. This can be done by a generous resection of the third rib paravertebrally.

Surgeons doing this type of work are specialists in vascular surgery or neurosurgery. An inquiry directed to any of the medical schools in Chicago will yield further information.

ERYTHROBLASTOSIS

To the Editor:—A normal baby, weighing 8 pounds 2 ounces (about 3,685 Gm.), was born by cesarean section (disproportion). Eight hours after birth severe jaundice developed in the baby (icterus index 135). A smear showed numerous erythroblasts and 70 per cent reticulocytes. Erythroblastosis was ruled out, the mother's blood being Rh positive. Subsequent smears showed typical spherocytes. A hematologist made the diagnosis of familial hemolytic jaundice, although the spleen and liver are not enlarged and the family history reveals only one typical attack of infectious hepatitis in the father. His blood smear did not show spherocytes. The baby at present (age 7 weeks) is normal in appearance, weighing 11 pounds 12 ounces (about 5,330 Gm.), and receives a routine formula plus 5 grains of ferrous sulfate daily. However, his hemoglobin which was 110 per cent (16.9 Gm.) at birth, has dropped to 55 per cent (8.4 Gm.). The following questions arise: 1. Is this a definite case of familial hemolytic jaundice in spite of the absence of enlargement of the spleen and liver and of a family history of the disease? 2. If the disease is present, how soon is splenectomy indicated? 3. Are blood transfusions indicated at present? 4. Is the iron added to the baby's formula of any value in preventing a further drop in hemoglobin? 5. What is the prognosis after splenectomy? 6. What are the chances that the disease may appear in the baby's offspring? 7. Have there been any new development in treatment aside from splenectomy?

Mauro Rosenberg, M.D., Sherman Oaks, Calif.

ANSWER.—No mention is made of a search for spherocytes in the mother's blood. Familial hemolytic jaundice may be passed on by either the father or the mother to the child. Spherocytes, if present, would be expected to persist in the blood stream rather than to disappear.

Though familial hemolytic jaundice does appear in the early age groups, it is extremely rare in newborn babies. Though splenomegaly may be absent, this is infrequent. In this disease, particularly in the early age groups, once jaundice has appeared it tends to persist or increase. In this infant, "normal in appearance," it is assumed that there is no longer evidence of blood destruction, namely jaundice, elevated serum-linked bilirubin or increase of urobilinogen in the stools, but only anemia. There is no mention of determinations of red cell fragility. From the evidence available, it is improbable that this is a case of familial hemolytic jaundice.

Erythroblastosis is not ruled out because the mother's blood is Rh positive. Some 5 to 15 per cent of babies with erythroblastosis are born of mothers with Rh positive blood. In these cases the Rh factor is of no etiologic importance, though the mechanism is similar. Antibodies develop in the mother against the baby's blood, the type having been inherited from the father. Blood types A and B are most commonly involved. If by passive transfer this antibody titer becomes sufficiently high in the baby's blood stream, blood destruction and erythroblastosis develop. It is possible that the case described falls into this category. However, with the meager evidence at hand, this conclusion cannot be drawn with certainty.

Since the child has survived seven to eight weeks, the prognosis is probably favorable. There is no indication for splenectomy. Small carefully typed and administered transfusions are indicated. Iron therapy may be of value.

NORMAL TEMPERATURE VARIATION

To the Editor:—A 5 year old girl has been having elevation of temperature, reaching 99.6 F. (orally), each evening for the past two weeks. There are no physical observations to account for this. Examinations of the blood and the urine revealed no abnormalities. A roentgenogram of the chest revealed no abnormalities. Can such temperature variations be considered within normal limits?

Oscar M. Plotkin, M.D., Elgin, Ill.

ANSWER.—The elevation of temperature to 99.6 F. (orally) each evening in a 5 year old girl may be considered within normal limits if all sources of infection, both acute and chronic, have been ruled out. Exercise is a frequent cause of elevation of temperature, both in children and in adults. This has been demonstrated in a young girl, whose temperature was 99.9 F. after thirty minutes of exercise, but after thirty minutes of rest her temperature fell. Children with neuropathic conditions respond more readily to an increased bodily temperature after exercise than normal children. These oscillations in temperature are so universal that they should be considered normal manifestations based on a somewhat unstable heat-regulating mechanism in young children.

LIMITATION OF SHOULDER MOTION

To the Editor:—What information is available on treatment of deltroid bursitis and tenosynovitis about arm and shoulder points? I am the patient, 62 years of age, physician, 6 feet 1 inch (185.4 cm.) tall; weight 206 pounds (93.4 Kg.). Had all the diseases of childhood; pneumonia, bilateral with delayed resolution in 1919, followed by mitral murmur, bronchitis and severe sinus disease. I have remained active until about ten months ago, when my arms and shoulders became limited in action because of the aforenamed trouble. Roentgen treatment gave no relief. Salicylates do no good and upset my digestion. I will greatly appreciate suggestions.

M.D., New Mexico.

ANSWER.—It is difficult to answer the inquiry because it is not clear from what precise condition the patient is suffering and the results of roentgenography are not stated. Shoulders can become painfully limited as a result of several conditions: rheumatoid arthritis of the glenohumeral articulation, osteoarthritis of the acromioclavicular joint, calcific or noncalcific tendinitis of any one of the four small rotator muscles, degenerative changes and tears in the musculotendinous cuff, tenosynovitis of the long biceps tendon, or the "shoulder-hand syndrome." Treatment varies widely, depending not only on the condition present but also on the stage (of acuteness or chronicity) of the condition and the amount of disability resulting therefrom. Space does not permit differentiation of these varying conditions.

Perhaps the lesion which most commonly produces painful limitation of shoulders in patients more than 45 or 50 years of age is calcific or noncalcific tendinitis of the supraspinatus tendon, a condition often erroneously called "subdeltoid bursitis." This condition is thought to result from the "wear and tear" of repeated minor trauma. Symptoms may be acute and extremely painful for a short time, or they may be chronic. Treatment during the acute phase consists of rest (often with temporary immobilization of the shoulder in the abducted and outwardly rotated position), local application of heat and the use of analgesic agents for symptomatic relief. To decrease digestive intolerance, salicylates may be taken with 3 to 8 fluidounces (89 to 237 cc.) of milk, or an alkali such as sodium bicarbonate in a dose equivalent to the dose of salicylate can be employed, or enteric-coated preparations of salicylate can be used. Roentgen therapy may be tried, since it sometimes gives additional relief of symptoms. Needling and the local injection of anesthetic solutions also are used in some instances.

When symptoms are chronically present, the measures which have been described are supplemented by more intensive physical therapy including heat, massage and active or active-assistant exercises designed to increase the range of motion. An exercise program, carefully prescribed and conscientiously followed, often is a neglected but important feature of the treatment. In most instances recovery of normal or nearly normal range of motion is necessary before pain and other discomfort are relieved. When adequate trial of conservative measures does not result in satisfactory improvement, manipulation of the shoulder with the patient anesthetized, or surgical exploration, may become indicated.

SYPHILIS

To the Editor:--I have a patient with latent syphilis with tabetic changes. I intend to give him 10,000,000 units of penicillin, injecting 300,000 units in Romansky's formula twice daily. In the light of latest experiences is this treatment sufficient or should it be supplemented with a preparation of bismuth or arsenic?

M.D., New York.

ANSWER.—The terms latent syphilis and tabes dorsalis are mutually exclusive. If the patient has " tabetic changes " he cannot have latent syphilis, which by definition is that form of syphilitic infection without symptoms or physical signs and manifested only by a positive serologic test. Before offering specific advice with regard to the patient in question, it is essential to know what are the tabetic changes with particular reference to a detailed account of symptoms, physical signs and examination of the spinal fluid, including cell count, quantitative protein estimation, quantitatively titered complement fixation (not flocculation) test and colloidal gold test. It is also important to be sure that the patient has no psychiatric manifestations of dementia paralytica. The effect of penicillin in tabes dorsalis can so far be measured only in terms of changes in the spinal fluid and amelioration of symptoms. Not enough time has elapsed since the introduction of penicillin therapy to be sure that this form of treatment will arrest further progress. In tabes, as in other forms of neurosyphilis, penicillin usually brings about prompt improvement in the abnormalities of the spinal fluid, especially cell count and protein content, which in about 90 per cent of cases return to normal within a few months. In the majority of cases, likewise, this improvement is maintained at least over a period of several years. Whether or not inactivity of the spinal fluid indicates the probability of arrest of the tabetic process cannot yet be determined. As to symptomatic relief in tabes dorsalis following penicillin therapy, this depends almost entirely on the individual symptom. There is about an even chance of some relief from lightning pains, which in some instances is only temporary. Other symptoms such as ataxia, urinary disturbances and impotence, are less favorably affected.

There are differences of opinion as to whether the treatment of tabes is best accomplished with penicillin alone or with penicillin plus induced malaria. A choice between these two methods of treatment may depend on the patient's physical condition. If this is sufficiently satisfactory to indicate that he may tolerate fever therapy without undue risk, it is probable that more significant symptomatic improvement will be accomplished by this than by penicillin alone; likewise, it is probable that arrest of the process will be accomplished. Perhaps a fair suggestion is that the patient be treated with penicillin first and, if improvement does not occur within a period of six months, retreatment be given with penicillin plus induced malaria. If penicillin in peanut oil and beeswax is employed, it is unnecessary to give the drug twice a day. A single daily injection of 600,000 units is ample. There is no indication for the use of bismuth and arsenic preparations in tabes dorsalis, since these drugs accomplish comparatively little in most cases. Finally, if the patient has primary optic atrophy, a common manifestation of tabes, time should not be wasted by treatment with penicillin alone. Penicillin plus induced malaria infection should be used from the start.

SWELLING OF PAROTID GLAND

To the Editor:—Regarding the query, " Swelling of the Parotid Gland", THE JOURNAL, February 14, 1948 we submit our opinion. In Mitchel-Nelson's " Textbook of Pediatrics" the complication of manubrial swelling in mumps is mentioned, and reference is made to the description by Gellis of its occurrence.

In a patient under our care we have seen a case similar to that described which occurred during an epidemic of mumps at a nearby Army post; we believe that this may well have been the same. One must also consider the possibility of scleredema (not scleroderma), though this is less likely.

John B. Reinhart, Captain, M.C., A.U.S.

To the Editor:--Regarding the query "Swelling of the Parotid Gland" THE JOURNAL, February 14, page 511, may I add the following note: The swelling described over the manubrium has been repeatedly observed in mumps and is apparently independent of the parotid swellings. I observed 3 instances in over 600 cases of mumps in an Army training camp. Case reports of this phenomenon have been published under the title of " presternal edema." It has been variously interpreted as due to thymic or thyroid involvement by mumps, or (more likely) involvement of the substernal lymph nodes producing obstructed lymphatic drainage of the presternal tissues. I have repeatedly observed fever and leukocytosis accompanying the onset of involvement of additional glands, or other complications of mumps; hence, this would not be a reliable criterion with which to rule out the disease.

Samuel Zelman, M.D., Topeka, Kan.

ARGYRIA

To the Editor:--In Queries and Minor Notes, THE JOURNAL, February 7, page 432, subject argyria, information was requested as to the use of 2,3-dimercaptopropanol (BAL) in the treatment of argyria. In April 1947 a patient at the Veterans Administration Hospital, Aspinwall, Pa., was given two courses of BAL in oil as treatment. No silver could be recovered in the urine after treatment; there was no change in the clinical appearance of the patient, and punch biopsy of the skin before and after treatment showed no change in quantity of silver in the tissue. It was concluded that BAL is unable to mobilize silver present in tissue in the metallic state and would consequently be of no use in the treatment of argyria. This was written up for publication. The unsuccessful use of BAL in treatment of experimental argyrosis in rats has already been reported (Olcott, C.T., and Riker, W.F.: Experimental Argyrosis. II. Treatment of Rats Receiving Silver with 2,3 Dimercaptopropanol (BAL), *Science* 105:67, [Jan. 17] 1947).

TREATMENT OF ACUTE FRACTURES OF THE NECK OF THE FEMUR

GEORGE W. VAN GORDER, M.D.
Boston

In discussing the subject of fractures of the neck of the femur, one must recognize at once certain "inevitables" which create a most difficult problem. These are (1) *the advanced age of patients affected by this* type of fracture, (2) the peculiar character of the bone that is directly involved, (3) the quality and distribution of the blood supply at the site of injury and (4) a weak anatomic location from the point of view of mechanics. One is handicapped at the very start with an old person, whose hip is broken in a place not only where the bone is narrowest and periosteal callous never forms, but where the blood supply is scanty and vulnerable and an enormous amount of mechanical strain is experienced.

The problem then, so far as treatment is concerned, is not an easy one to solve and, despite all efforts, still remains a challenge. To be sure, we surgeons have progressed far since the old days of sandbags, wooden splints and Buck's extension, and even passed a milestone when Whitman[1] advocated his abduction method of treatment, but, fortunately, we did not stop there. Instead, we have traveled on to a new and more hopeful solution, and have at present reached what may be considered another milestone of progress—the treatment of these fractures by means of internal fixation.

This new concept of treating fractures of the neck of the femur was presented by Smith-Petersen[2] in 1931 and, in the course of time, has gained almost universal acceptance. Many surgeons, as Harry Platt of Manchester, England,[3] have expressed the opinion that internal fixation with the Smith-Petersen triflange nail has entirely revolutionized the treatment of fractures of the femoral neck, giving a higher percentage of bony union, extending the scope of effective treatment in older and more frail patients, reducing the primary mortality and affording greater comfort in after-treatment. Or, as Watson-Jones[4] put it, "There can be no doubt that Smith-Petersen's discovery has not only revolutionized the prognosis of this injury from the point of view of union of the fracture, but is also to be regarded as a life-saving measure."

Similar optimism has been expressed in many parts of the world, including America, and I hope with justification, but we cannot be sure of our ground until the pitiless light of experience is shed on the facts and reveals the naked truth. Hence this symposium today.

It is high time that we took stock and decided where we are at present and how far we have yet to go; in order to do this, we must direct our thought first to the treatment of the acute type of fracture of the femoral neck.

SELECTION OF PATIENTS FOR OPERATION

Fortunately, few patients with fracture of the neck of the femur are ineligible for the operation known as hipnailing. In some clinics, it is only the moribund or acutely ill that are deprived of its advantages. Certainly, the patient's age alone has proved to be no contraindication—as is well known to all who have had patients over 90 years of age that not only have survived the operation, but have continued to live in comfort for years following it.

Groves[5] is not convinced that anything is to be gained by operative treatment of this fracture in the extremely old and feeble persons, and suggested Russell traction for these, but other authorities expressed the belief that hip nailing is especially applicable to the aged and infirm because, in spite of greater risk, it may be lifesaving Thomas King[6] of Australia stated that unless the patient was bedridden or moribund every intracapsular fracture under his care has been treated by operation. However, he always withheld operation when the temperature was raised or pulmonary changes were present.

E. I. Lloyd[7] warned against attempting to cure pneumonia in moribund old women by nailing, but Brittain[8] advised it, and Thornton and Sandison[9] also did not defer operation on this account, and they recorded no deaths in 60 patients. As the operation is not dangerous, especially when done with the patient under local anesthesia with a minimum of gas-oxygen and with the aid of chemotherapy, they stated their belief that it is humane to operate and relieve the patient's pain—thus allowing more effective nursing of the pulmonary condition in the lateral and Fowler positions.

Certainly it is true, as King[6] stated, that never before have so many fractured femoral necks been treated with the object of obtaining osseous union, and yet the general mortality has not been increased by operation, but actually decreased. It is fair to conclude, then, that because of the comfort which it gives the patient and the minimum of risk involved, hip nailing is indi-

cated for all patients, irrespective of their age, who have a fracture of the neck of the femur—provided that they are not acutely or hopelessly ill.

PROPER TIME FOR OPERATING

There has been a great difference of opinion among surgeons as to the proper time for operating in these cases, varying from immediate operation as an emergency procedure to waiting three weeks, in order to assess the patient's physical status and escape the high early mortality associated with fractures of the hip. So far as end-results are concerned, there seems to be no appreciable difference between those patients operated on immediately and those operated on within a two or three week interval. In fact, Eyre-Brook and Pridie[10] reported osseous union in patients whose hips were nailed as long as thirty-three days after injury. Nevertheless, it seems logical to assume that the sooner the broken hip is nailed, the sooner will the patient be made comfortable, and the sooner will an improved circulation be established at the site of the fracture. Also, by early insuring the patient more freedom of activity, numerous complications may be avoided during convalescence.

Most writers on this subject agree that as soon as the patient is declared suitable for operation the procedure should be carried out. No mad rush is advocated, but a delay of more than one week is not generally considered advisable.

TYPE OF ANESTHESIA

There is apparently no uniformity of opinion among surgeons as to the ideal form of anesthetic to be used during the operation for fracture of the neck of the femur. Practically every kind of an anesthetic is mentioned by various writers, and none in particular is condemned. It is fair to state that, from data obtained in the recent literature, the majority of surgeons who treat this type of fracture use either spinal or some form of general anesthesia for patients under 60 years of age who are in good health. For the extremely old, feeble patients and in risky cases, however, their choice would be local anesthesia supplemented by gas-oxygen or ether at the time of the reduction of the fracture and during nailing, when complete relaxation is necessary.

TECHNIC OF REDUCTION

The importance of obtaining an accurate reduction in fracture of the neck of the femur cannot be overemphasized. Many surgeons have stated the belief that success or failure of treatment depends almost entirely on this one factor alone. Experience also would lead to the conclusion that the more accurate the reduction, the better the chances of union, and the poorer the reduction, the greater the chances of nonunion.

It behooves every surgeon who treats this fracture, then, to obtain the best possible reduction of it and, in order to do this, he must first study carefully its characteristic and distinctive features. This is not possible, as a rule, with the use only of the original roentgenograms, because in them the fracture lines are often overlapped and distorted, but after the use of traction for twenty-four or forty-eight hours, with the correction of external rotation of the limb, new roentgenograms can then be taken by a portable roentgen unit in both the anteroposterior and lateral planes, which will reveal not only the exact location of the fracture, but its obliquity and degree of comminution. It is most essential to have this data prior to operation, since such information often will determine the kind of manipulation that will be most effective in the reduction of the fracture.

It might be well to mention here the possible danger of overpulling by means of preliminary traction. Only moderate traction is necessary, as a rule. Thus, a 6 or 8 pound (2.7 or 3.6 Kg.) weight with Russell traction would be ample, depending on the size of the patient, and skeletal traction should never be required. The danger in overpulling is that the torn capsule may become stretched and elongated and that the femoral neck and head cannot then be controlled by the usual reduction maneuvers. King[6] found this to be true in a case in which finally open reduction was necessary.

As was mentioned, a careful study of the patient's roentgenograms after preliminary traction will aid in determining the proper manipulation maneuver to employ for reduction. In a great many instances, this will mean that only light manual traction on the limb, followed by internal rotation, is all that is necessary. In other instances, where a rotation of the fragments has to be corrected, the Whitman[1] method of reduction—extension, internal rotation and abduction—may have to be carried out.

If, in addition to a rotation deformity, there is overriding or shortening of the femur, then frequently the Leadbetter[11] method—hip flexed to 90 degrees, upward traction in the axis of the flexed thigh, together with slight adduction of the femoral shaft, followed by internal rotation of the thigh to 45 degrees, then circumduction into abduction, maintaining the internally rotated position—will be more effective. Many surgeons use the Leadbetter maneuver routinely for all types of central fractures of the neck of the femur, but it is perfectly apparent, that, since no two fractures are identical, it is unreasonable to expect that any single method of reduction will be suitable or adequate for all fractures of the femoral neck.

An attempt should be made at the time of reduction to procure a valgus position of the broken fragments of the neck, if this is at all possible, since the position of valgus creates a "pressure" rather than a "shearing" force at the line of fracture and will aid in securing union. A little additional pull on the leg will sometimes accomplish this by causing the femoral head to rock into a position of valgus, which is advantageous, but too much traction—just as too much abduction—can have a detrimental and deforming effect. One must be careful about the degree of abduction and not overdo it.

Whether the reduction is satisfactory must be determined by clear roentgen views of the fracture, both in the anteroposterior and lateral planes, which requires considerable time and is one of the chief bugbears in the treatment of this fracture. Just a passing glance at the wet roentgen films is not sufficient; neither are indistinct and uncertain outlines of the femoral head and neck to be considered acceptable. One must exercise patience at this stage of the procedure and insist on accuracy—both as regards bone detail in the roentgenograms and reduction of the broken fragments. Should any deformity remain after reduction, further manipulation must be carried out, until the deformity is completely corrected. This may require various maneuvers and tax the skill of the operator to its utmost, but unless the reduction is accurately obtained the operation of nailing or pinning should not be carried out, unless done by the open method—which will allow manual reduction under direct vision.

[10] Eyre-Brook, A. L., and Pridie, K. H.: *Intracapsular Fractures of the Neck of the Femur: Final Results of seventy-five Consecutive Cases Treated by the Closed Method of Pinning*, Brit. J. Surg. 29:115-138 (July) 1941.

[11] Leadbetter, G. W.: *A New Method of Treatment for Fracture of the Neck of the Femur*, J. Bone & Joint Surg. 15:931-940 (Oct.) 1933.

Probably the most difficult and unsatisfactory fracture of the femoral neck to reduce is the subcapital vertical type, in which the inferior edge of the proximal fragment projects as a spur or prong below the corresponding surface of the distal fragment (fig. 1). Such a fracture allows mechanically the greatest amount of "shearing" force possible, and for this reason, as well as the difficulty of obtaining an accurate reduction, it often fails to unite following nailing.

McElvenny[12] recognized the importance of this type of fracture and urged extreme care in its reduction, making certain that the distal fragment of the neck be placed well below and mesial to the proximal fragment. To accomplish this, it may be necessary to reverse the usual reduction maneuver and, after placing heavy traction on the leg in order to draw down the distal fragment, to adduct the limb so as to allow the spur portion of the proximal fragment to engage the distal fragment at a point above, and not below, its inferior border (fig. 2). This maneuver, followed by abduction, will impact the two fragments in a position that will produce less of a shearing force and more of a pressure one. Other surgeons, when confronted with this vertical type of fracture of the neck, are inclined to agree with King[6] that a bone graft should be used at the time of operation, in addition to the Smith-Petersen nail (fig. 3). McMurray[13] and a few others would immediately resort to an osteotomy rather than nail this type of fracture, which gives so little hope of future osseous union.

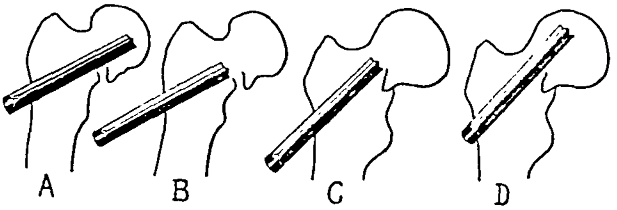

Fig. 1.—A, vertical type of fracture, with spike attached to caput femoris; bad prognosis, even with nailing. B, nail withdrawn to fracture line preliminary to manipulation. C, following manipulation (fig. 2) spur of caput femoris has been locked and impacted in cancellous bone of distal fragment. D, nail driven home.

After an accurate reduction has been obtained, some means of maintaining it during the process of nailing or pinning must be employed. Some use a fracture table for this purpose; others skeletal traction; others find manual traction by an assistant adequate and satisfactory. The advantage of having an assistant hold the involved leg is that, in addition to maintenance of the femoral shaft in the proper degree of internal rotation and abduction, the knee can be flexed and held at a right angle—thus helping to lock the fragments of the head and neck in position, by tightening the extensor group of thigh muscles.

It might be mentioned here that only a few fracture clinics in the world continue, at the present time, to reduce fractures of the neck of the femur by the open, operative method. Smith-Petersen,[2] who was the first to advocate this method, gave it up as a routine procedure in 1934 for the closed, extra-articular technic suggested by Westcott[14] and known as "blind nailing."

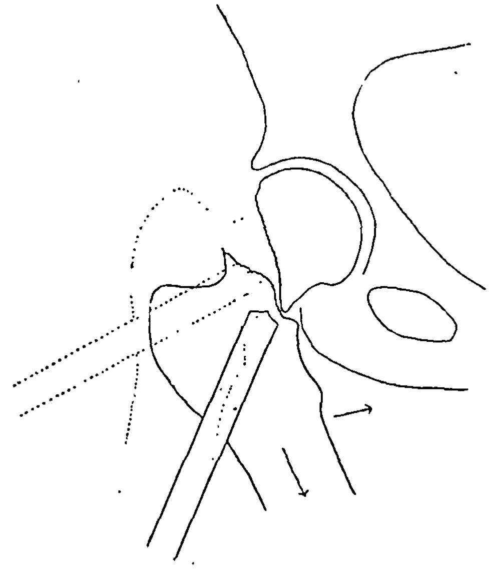

Fig. 2.—Diagram of manipulative procedure. Shaft of femur is pulled down and adducted in order to lock spur of caput femoris inside cortex of distal fragment. The fragments are then impacted by abducting the leg.

More recently, in 1935, Mr. R. Watson-Jones[15] of Liverpool, who was a strong advocate of open nail fixation, has also abandoned this method in favor of the "blind" operation—not so much on the grounds of simplification of technic as on the conviction that the less the fracture site was disturbed by the surgeon, the better. Most surgeons feel that a satisfactory reduction can usually be obtained by the closed method and that the "blind nailing" procedure produces the least amount of trauma to the patient and the least disturbance of the circulation at the site of fracture. The chances that

a portion of the joint capsule will become interposed between the bone fragments after reduction, are so rare that this possibility, in itself, is not considered an adequate argument for the necessity of routine open reduction.

If, despite one's best and repeated efforts, an accurate reduction of a central fracture of the femoral neck cannot be effected, then two courses of procedure remain open to the operator—an open reduction or some form of osteotomy. McElvenny prefers immediate osteotomy if he fails to reduce the hip fracture or is in doubt as to the effectiveness of the reduction, while others prefer a trial at open reduction in such cases before resorting to either osteotomy or some form of reconstruction operation.

TECHNIC OF OPERATION

Here the old dictum "Every man to himself" applies with more than a grain of truth, for hardly any two fracture clinics in the world employ identical technics in the operation of internal fixation of hip fractures. It is not the purpose of this paper to discuss the relative merits of these numerous and various technics, or to mention all the materials used for internal fixation—such as lock bolts, stud bolt screws, lag screws, nails, various kinds of pins, wires and bone grafts. Nor will I be permitted in the time available to speak of the dozens of ingenious guides that have been invented for placement of the guide wire or Smith-Petersen nail.

The impression one gets in reading about so many of these different technics and pet gadgets is that the treatment of these fractured hips has become much too highly specialized and that a need for standardization is real. It is hoped that with the continuation of study on the end results of these fractures by orthopedic association committees one or two methods will be found so outstanding in their superiority that they alone will eventually be employed and standardized.

For the purpose of this paper, I will confine my remarks on the subject of operative technic to the type of procedure that is now used by the majority of the orthopedic staff at the Massachusetts General Hospital with the Smith-Petersen nail. Most of us used a guide wire technic, but Smith-Petersen and a few others prefer nailing without the guide wire.

Procedure.—The patient is anesthetized on an ordinary operating table, with an x-ray cassette or tunnel under the hips, after which the unaffected leg is flexed at the hip and its lower end comfortably placed on the arm of a portable x-ray machine that rests between the patient's legs and is aimed at the opposite, broken hip. The operator then carries out his reduction maneuver on the broken leg, placing it finally in the hands of an assistant, who is sitting beside the operating table and facing toward its head. While the assistant puts light traction on this leg in a position of slight abduction and internal rotation and with the knee flexed at right angles, roentgenograms of the fracture are obtained in both anteroposterior and lateral planes. This requires the use of two portable x-ray units, one previously placed under the good leg for the lateral view and the other a movable unit which can be swung over the hip area when needed for the anteroposterior view.

If the reduction of the fracture is considered to be satisfactory, the skin of the operative field is then prepared and draped, and the operation continued; if not satisfactory, the manipulation is repeated, being governed by the degree and character of the deformity remaining.

After accurate reduction and preparation of the operative field, a lateral incision about 5 inches (12.7 cm.) long is made over the greater trochanter and carried down to bone through the split fibres of the vastus lateralis muscle. This exposure allows ample room for the placement of the Smith-Petersen nail, and after the point for penetration of the cortex is determined, Westcott's[14] protractors or an anatomic marker is used for estimating the angle at which a 3/32 inch (0.48 cm.) guide wire should be introduced into the femoral neck and head. Care is taken not to drill this wire so deeply so as to penetrate the joint cavity. New roentgenograms are now taken in both planes to determine the location of the guide wire and whether it is placed properly—by which I mean through the lower half of the neck, parallel to the calcar femorale and centering in the proximal portion of the femoral head in both planes. A Smith-Petersen nail marker is then threaded over it and small cuts are made deeply into the femoral cortex with a fine osteotome, corresponding to the flanges of the nail. A cannulated nail of correctly measured length is now substituted for the marker and driven home over the course of the guide wire. Impaction of the fracture is then done, and a final set of roentgenograms taken to make sure that the nail is well centered and of proper depth, and that no distortion or angulation of the head has occurred.

If the roentgenograms show the first guide wire to be incorrectly placed, successive wires are introduced at the estimated proper angle and distance and new roentgenograms taken, until the operator is absolutely satisfied with the final position. Not until then should nailing proceed, keeping in mind Mr. Eric Lloyd's aphorism, "The bad results of nailing are the results of *bad nailing.*"

Whenever a fluoroscopic table is available in the operating room, I prefer to do the reduction and fixation on it. The table x-ray unit is utilized for anteroposterior views and a portable unit is used for the lateral views. Direction of the guide wire is facilitated by inserting it under intermittent fluoroscopic vision, which is controlled with extreme care and requires only a second or two. The position is then checked in both planes by ordinary roentgenograms. A roentgenologist, or trained associate, supervises the fluoroscope and judges the direction and depth of the guide wire and nail. The operator checks all necessary observations, however, by clear roentgenograms. This arrangement saves a great deal of time and, in my experience, is the ideal technic for hip nailing. In one sense, it is a two man job, but because of this team work, fewer errors are made and greater accuracy is obtained.

POSTOPERATIVE CARE

The postoperative care of patients whose hips have been nailed varies tremendously in different clinics, from no external support of any kind for the hip following operation to protection in bed with leg traction for periods up to three months. A few surgeons prefer to get their patients up the day of operation or the following day, and one has stated that "in a few hours the patient is ready for a wheelchair and may at once, if so disposed, enjoy the use of crutches." Such heroic measures are, fortunately, not endorsed by orthopedic surgeons in general. I agree with many of my colleagues, who term such drastic procedures "stunt surgery." To be sure, it may be necessary on rare occasions gently to lift a feeble patient into a chair for short periods of time, being extremely careful to support the affected leg, but as a rule this is neither necessary nor advisable.

Watson-Jones[9] protects the operated leg in bed by attaching a wooden crossbar to the heel of the patient's slipper or shoe, which necessitates the leg's resting flat on the bed at all times, and prevents any external rotation. He expressed the belief that traction in a Thomas splint is dangerous in these cases, because of the long leverage that can place strain on the hip. Eyre-Brook and Pridie[10] use no external fixation of any kind, but allow the leg to rest on a pillow.

Still others, as McElvenny,[12] have stated their belief that no attempt should be made to hurry these patients out of bed; if the patients have done well in bed, McElvenny keeps them down from three weeks to twelve weeks—depending on their age, size and ability to handle themselves. Exercises and physical therapy were started about the fourth postoperative day, however.

The practice in the Massachusetts General Hospital Fracture Clinic has been to place these patients, after their operation, back in traction for one month, then to remove the traction, but to keep them in bed for another two weeks. At the end of six weeks, they are taught to walk with crutches, allowing the foot of the affected leg to touch the floor but not to bear any real weight. No walking caliper splints have been used. Subsequent roentgenograms determine whether full weight bearing shall be permitted at the end of four months, or later. In most cases, it is considered safer to wait until at least six months have elapsed before discarding crutches. In other words, we feel, as does Watson-Jones,[4] that early weight bearing is not imperative and may be dangerous.

PROGNOSIS

In order to discuss the prognosis of these fractures, a word or two should be said about their classification. Many classifications have been suggested for fractures of the femoral neck, particularly according to their location, but the only difference among them all is in the names, not the location. Suffice it to say that most writers now speak of the three main regions of the femoral neck relating to fractures as being the subcapital, central and basal, and the subdivisions of each fracture as being either horizontal, oblique or vertical in type, with or without comminution.

It is common knowledge that not only the location, but the nature of the fracture itself has a great deal to do with its reaction to treatment. Basal fractures, for instance, if accurately reduced and fixed adequately, will invariably unite. The same can be said of impacted fractures, although it must be remembered that roentgen evidence alone of impaction is not adequate or reliable grounds for an absolute diagnosis of this condition.

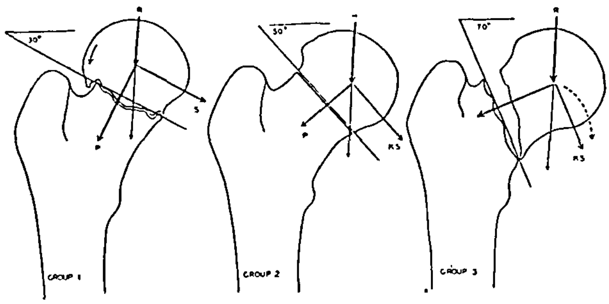

Fig. 4.—Group 1, impacted type of fracture; fracture line less than 30 degrees to the horizontal; no shearing force; good prognosis. Group 2, fracture line 30 to 50 degrees to the horizontal; some shearing force; requires accurate reduction and perfect nailing. Group 3, fracture line 50 to 90 degrees to the horizontal; prognosis bad, even with nailing. This type of fracture should be grafted in addition to nailing, or else be treated by osteotomy. (From Pauwels.[10])

F. Pauwels,[16] in his excellent monograph, "Der Shenkenhalsbruch, ein mechanische Problem," expressed the view that the obliquity of the fracture line is of paramount importance, so far as prognosis for osseous union of the fracture is concerned. For instance, he divided central neck fractures into three groups (fig. 4): (1) impacted fractures (fracture line less than 30 degrees to the horizontal) in which no shearing force occurs; the prognosis is good and no nailing is necessary; (2) fractures with their obliquity line between 30 and 50 degrees to the horizontal, in which there is some shearing strain unless the fracture is nailed; (3) vertical fractures, in which the obliquity of the fracture line is from 50 to 90 degrees to the horizontal. In these latter fractures, a long beak or spike is usually attached to the inferior edge of the caput femoris, and the prognosis is bad, even with nailing, unless a solid fibular graft is also used in the upper third of the femoral neck (fig. 3).

Pauwels' theory has had far reaching influence, not only in Germany, but in England and Australia as well. Here in America, a similar idea has been suggested by McElvenny,[12] and all of us who deal with this problem surely feel as do Thomas King,[6] A. L. Eyre-Brook,[10] K. N. Pridie [10] and others that Pauwels' group 3 fracture, the vertical type, presents the most difficult problem of all to solve. Eyre-Brook and Pridie[10] found that they had no complications in any of their fractures of the femoral neck that had an obliquity angle of less than 53 degrees to the horizontal, and they expressed the opinion that the importance of this angle clearly outweighs nearly every other factor and should control the treatment given (fig. 5). In other words, they stated their belief that when the obliquity angle is over 70 degrees to the horizontal (50 to 90 degrees, Pauwels), some modification of the pinning operation should be employed—either the addition of a bone graft or a subtrochanteric osteotomy to decrease the obliquity angle.

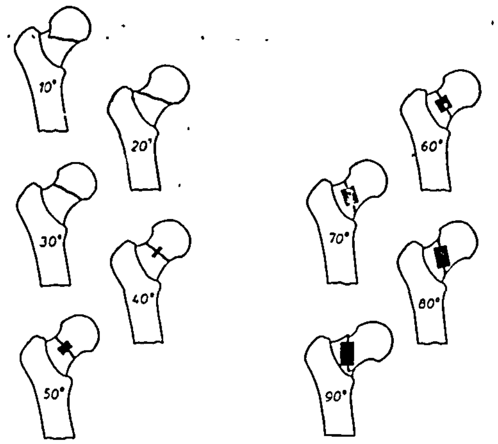

Fig. 5.—Fractures of the femoral neck with different angles of obliquity. When the angle is less than 50 degrees to the horizontal, the prognosis following nailing is good; when it is more than 50 degrees to the horizontal, the prognosis with nailing alone is poor, and there should be a bone graft as well or an osteotomy should be performed. (From Pauwels.[10])

Pauwels' work is most impressive and has led many surgeons throughout the world to consider seriously whether the end result of fractures of the femoral neck is not controlled by the nature of the fracture almost as much as by the surgeon and his nail or pins.

Another important influence affecting the prognosis of fractures of the femoral neck from the point of view of life expectancy is nursing care. We are all aware that these aged patients can and do survive the operation of hip nailing surprisingly well and can live on after it, provided they have excellent nursing care, but as soon as they are deprived of a high standard of hospital nursing and are sent away to a nursing home or to other institutions for the aged, they begin to fail and soon die.

---

16. 'Pauwels, F.: Der Schenkenhalsbruch, ein mechanische Problem monograph.'

Thus far, an attempt has been made to survey various factors that enter into the treatment of acute fractures of the neck of the femur. Just how much we have accomplished, how successful we have been and how much further we have to go in order to solve our problem will be learned from the papers that deal with end results and which are now to follow in this symposium.

CONCLUSION

In closing, it would seem fitting to enumerate the following things that we have learned about the treatment of acute fractures of the neck of the femur since the advent of the hip-nailing operation sixteen years ago: (1) that age is no contraindication; (2) that the optimum time for operation is within one week of the injury, and the earlier the better, all things being equal; (3) that accurate reduction of the fracture is of paramount importance, since the more accurate it is, the better the chances of union, and the poorer the reduction, the greater the chances of nonunion; (4) that skeletal traction or a traction table is not necessary to reduce fractures of the neck of the femur or to maintain the reduction while they are being nailed; (5) that, after manipulation and reduction of the fracture with the patient under anesthesia, manual holding of the fractured leg by an assistant, with the thigh extended, the knee flexed at right angles and internal rotation and abduction of the femoral shaft, is adequate; (6) that the most difficult fracture of the femoral neck to reduce and treat successfully is the subcapital, vertical type; this being so, its treatment by nailing should be supplemented by bone grafting, or else some form of osteotomy should be performed; (7) that fixation materials (nails, screws, pins, etc.) should be made of metals which produce no ionization in the tissues; (8) that arthrotomy is not necessary for nailing the majority of fractures of the neck of the femur; (9) that the operation can be performed with little trauma or shock; (10) that the proper position for the Smith-Petersen nail is along the lower half of the femoral neck, its sharp end centering in the proximal portion of the head of the femur in both the anteroposterior and lateral planes; (11) that the lateral roentgen view is indispensable in determining the reduction of the fracture and the placement of the nail; (12) that it is rarely necessary to drive the guide wire across the joint line into the acetabulum in order to control rotation of the femoral head when nailing; (13) that if multiple wires or pins are used for internal fixation of the fracture some form of retention apparatus—such as a nut threaded on the ends of the wires—must be employed to prevent them from wandering out of their position; (14) that patients can be gotten out of bed the day of operation or the day following, but that this procedure is not necessary as a rule, is often ill advised and should be employed only in exceptional instances; (15) that the prognosis of fractures of the neck of the femur depends, to a large extent, on their location, their obliquity, and nursing care; (16) that, according to the most reliable reports in the literature, internal fixation methods of treating fractures of the neck of the femur result in a higher percentage of bony union and a much lower mortality than do other methods such as those of Whitman, Roger Anderson, well leg traction, Carl P. Jones traction and the Wilkie boot.

MANAGEMENT OF THE TROCHANTERIC FRACTURE OF THE FEMUR

MATHER CLEVELAND, M.D.
D. M. BOSWORTH, M.D.

and

F. R. THOMPSON, M.D.
New York

Many erroneous concepts are common as regards fracture of the trochanter. Perhaps that most frequently met is that the trochanteric fracture is a simple lesion, easily handled and usually with good result. Under such a concept a good result must be accepted as that in which the patient escapes with life and deformity. Disability and discomfort during the final ensuing years are disregarded. Only on a percentage basis of an adequate number of cases treated may one rightly draw conclusions as to what constitutes the best mode of treatment with the most satisfactory results obtainable. In a recent survey of 133 consecutive cases treated on the orthopedic service at St. Luke's Hospital this lesion was shown not to be simple and not to eventuate routinely in a satisfactory result. Percentages of results could be and were estimated from this group. Often bitter experience led to the conclusions. These we shall later enumerate.

Patients with this fracture are an elderly group. Their average age is above 75 years. This places their age as more than twelve years above that of the average of patients with intracapsular fractures of the neck of the femur. Few years of life expectancy are left. Ninety per cent of the patients are women, a fact probably explained by the less rugged bony structures and usually more pronounced atrophic osseous changes in women. As would be expected, these old persons represent a veritable museum of pathologic changes aside from their fracture. Serious and commonly associated lesions include cardiac, diabetic and senile mental changes. Renal lesions, crippling arthritis, syphilis, carcinoma, hemiplegia and many other afflictions of the aged are present. A "good risk" for any form of treatment is a rarity.

TYPE OF INJURY PRODUCING THE FRACTURE

Injury is generally trivial, consisting of a simple fall, tripping over a rug, slipping out of a chair, etc. Occasionally direct violence is responsible. Most fractures of this type occur by dissolution of continuity of bony structures preceding the fall and are not the result of the fall. Perhaps the main contributing factor to such injury lies in the elderly person's inherent instability while erect and her slow reflex response. Despite the poor outlook for these patients, their response to rapid and definitive treatment for the relief of pain and spasm is good. Their resistance even to rather extensive surgical procedure when rapidly carried out and bolstered by supportive measures is excellent.

FACTORS MODIFYING THE MODE OF MANAGEMENT

There can be no question but that on a countrywide basis all such patients cannot be treated alike to secure the most favorable results. Many such fractures must of necessity be cared for in small or rural communities

---

Read in a panel discussion on Fractures of the Upper End of the Femur before the Section on Orthopedic Surgery at the Ninety-sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1947.

where transportation is impossible and surgical help unobtainable. The experience of the available medical and surgical personnel must always have a strong influence on the mode of treatment to be selected. The equipment available is not such an important factor, since any of the hereinafter enumerated methods of treatment may be used, even in a small home in a farming community, except that of open reduction and fixation.

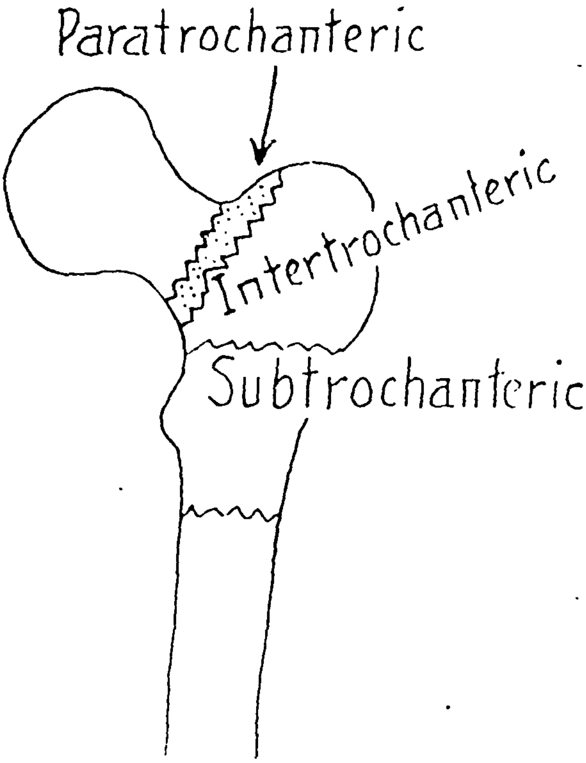

Fig. 1.—Trochanteric fractures may be roughly divided into three main classes, depending on the location of the major point of bony injury.

The type of trochanteric fracture (fig. 1) will to some extent influence the mode of treatment. It will, however not so greatly influence the mode of treatment as it will the end result to be secured and the length of time required for union. The paratrochanteric fracture will tend to result in a final external rotation deformity The pertrochanteric fracture may evantuate in shortening with external rotation deformity. The subtrochanteric fracture will tend to be difficult to control and finally may result in rotation deformity, shortening and angulation.

MODES OF TREATMENT

Simple support by sandbags, pillows, etc. has long been used in the past for these fractures and still is occasionally used. Splinting the broken extremity to the opposite well leg likewise is occasionally accepted. Both measures are antiquated. Though occasionally still employed because of a fatalistic outlook that certain patients cannot recover and that facilities of nursing and care cannot be obtained, they should be discarded completely.

A simple Buck extension or adhesive leg traction may be condoned. It is, of course, unacceptable where facilities for other forms of treatment exist, but will give relief from pain and spasm. It will allow a certain amount of motion of the patient and facilitate nursing care. This simple traction is easily understood by the family and friends, and if properly applied and occasionally supervised may lead to a favorable result. For rural communities and for the patient who because of stubbornness, senility or other reason refuses to leave his home, it is adequate, though barely so.

Russell's balanced traction, though it seems complicated at first to the uninitiated, may be readily understood and is easily applied. Where more advanced treatment is impossible, it provides the same comfort as simple traction and a far better outlook for recovery without crippling deformity. This method of applying traction has come into such widespread use that, pending other facilities for the treatment of these patients, there is but little excuse for not employing it even under decidedly adverse situations. The last two modes of applying traction are simple, promote comfort and, to a considerable extent, provide adequate management of the patient. They do not provide for mobilizing the patient.

Well leg traction may be applied by numerous forms of apparatus or, indeed, with no apparatus at all save for plaster bandages and a basswood splint. Adequate well leg traction necessitates one simple surgical operation. Traction cannot be satisfactorily applied over a long period of time merely by boot application and traction on the injured limb through the pressures exerted by the boot on the foot. Transfixion of the injured femur with a Steinman pin to be incorporated in the upper portion of the traction boot is a necessity. Sterile procedures in the insertion of this pin and adequate dressings are of primary importance. Not only this, but at time of removal of the pin adequate sterile procedures must be provided to avoid infection. Immobilization of uninjured joint structures results from the use of this method and greatly complicates the postoperative period of recovery and eventual outcome. For this reason, though we used the method for three years in consecutive cases at one institution, and sporadically at many others, we have discarded it and would discourage its application. Russell traction is fully as adequate, is much simpler and produces many less complications. Well leg traction has one advantage that methods previously mentioned do not. With such apparatus in place the patient is transportable either from bed to bed or from house to house. Despite this the unfavorable aspects outweigh this advantage.

One may not disregard the plaster spica advocated by Whitman and its use for the trochanteric fracture. By this method the patient for the first time may become ambulatory. The same faults, however, appear as in the use of well leg fraction. Joints are immobilized and stiffened over weeks and months. Though union may be obtained, the results are better with balanced traction and far better with internal fixation. Not only this, but frequently the patient with a spica does not become ambulatory, and, if the patient be obese, cast retention may be impossible. After the chest, abdomen and extremity have been covered with a cast, other complicating lesions can neither be studied and evaluated nor treated. One would hesitate to discard the use of this form of treatment entirely, since under certain circumstances and in the favorable type of patient its use might prove of great worth either temporarily for transportation purposes or permanently where necessity decreed.

INTERNAL FIXATION

Internal fixation in treatment of such fractures at first gained whirlwind acceptance and as rapidly declined in favor. The problems and disadvantage of fixation by wires, threaded wires, pins, screws and screw apparatuses rapidly forced it into the discard. Surgeons returned to an acceptance of balanced traction, well leg traction or the plaster spica. Then, following the demonstration of successful use of the Smith-Petersen three-flanged nail for intracapsular fractures of the neck of the femur, experimentation with a similar nail plus an attached or attachable plate for trochanteric fractures gradually developed. This form of treatment we now favor for routine use wherever surgical experience, equipment and outlook for continued existence of the patient make it possible.

RESULTS OF INTERNAL FIXATION AND TRACTION COMPARED

We have recently completed a survey of what we believe to be the most favorable form of conservative treatment of the trochanteric fracture, namely, balanced traction, and of internal fixation with the three-flanged nail. The nail used has a solidly affixed plate as designed by Jewett for fixation of the head and neck portion of the fracture to the shaft. A 94 per cent follow-up of 133 consecutive cases was carried out. One group of 38 patients treated by traction was compared with a second group of 95 patients treated by internal fixation. The final result is accurately known in all of the latter group. The study covered an eight and one half year period. The great bulk of the fractures were pertrochanteric (fig. 2) and generally comminuted (80 per cent). The rest were subtrochanteric (fig. 3), paratrochanteric (fig. 4) and combinations of the foregoing.

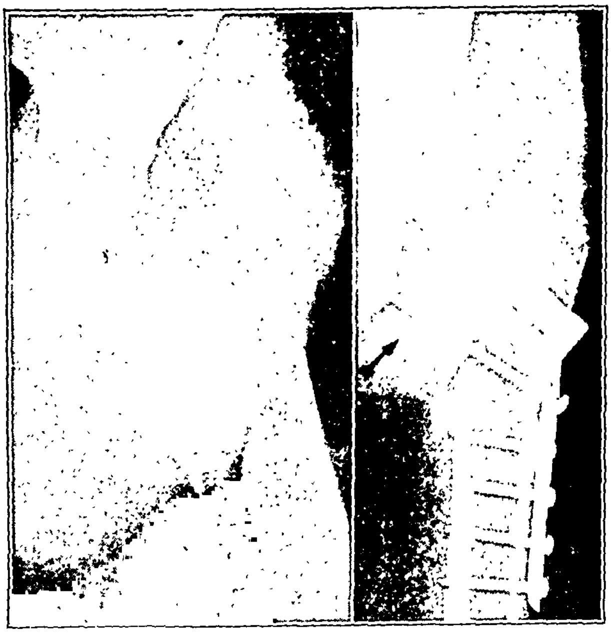

Fig. 2.—Pertrochanteric tractures constitute the majority. Nail placed in the lower portion of the head and neck and centered on lateral view (not shown) constitutes optimum position. Lesser trochanter can occasionally be affixed in place. The photograph on the right was taken seven weeks postoperatively.

Decision to attempt internal fixation as a method, replacing balanced traction, was made on a review of the records of the traction patients. A great many unsuspected complications appeared on their follow-up. Despite excellent nursing care, pressure sores over the sacrum and buttocks were the rule rather than the exception. Cystitis, bladder complications, residual stiff knees, hip contractures, permanent vascular changes, peroneal nerve palsies, muscle atrophy, senile psychoses, prolonged general inanition and debility and a high mortality were disclosed. A critical follow-up review shattered our complacency as regards the efficacy of conservative treatment and the end results secured. From past experience with the use of internal fixation with wires, screws, pins, etc., we were not sure that improvement could be gained with the angled nail. Despite this, trial seemed warranted. The flanged nail was chosen since the simple straight nail was unsatisfactory as inapplicable to the vast majority of these comminuted or displaced fractures. Pins, threaded pins, wires and screws had been discarded years previously as lacking stability. The three-flanged nail with plate affixed by nut or bolt was found to lack stability at the junction of nail and plate, and after trial was discarded. The Jewett nail was finally used and with a few minor structural changes has proved acceptable. It should be of "vitallium" or other nonelectrolytic metal. For satisfactory application such nails must be at hand with

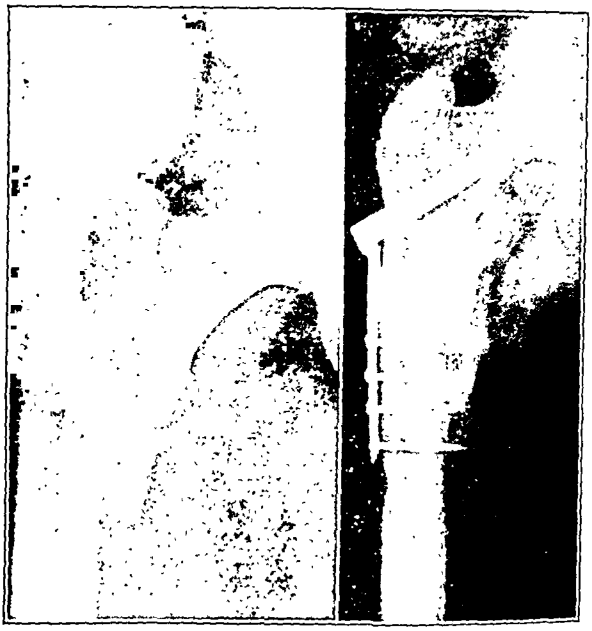

Fig. 3.—Subtrochanteric fractures, so difficult to maintain in position are easily held by the Jewett nail. The photograph on the right was taken four and one-half months postoperatively.

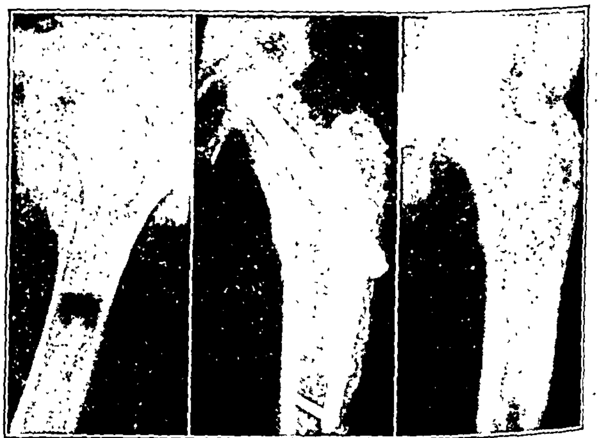

Fig. 4.—Paratrochanteric fractures reduced by the nail are maintained without deformity of neck angle or rotation. Nails occasionally may be removed though usually are left in situ. The center photograph was taken nine months postoperatively, and the photograph on the right two and one-half years.

three angles and in two lengths to accommodate the various types of fractures. With such nails the comminuted paratrochanteric and intertrochanteric fracture can be adequately stabilized as well as the subtrochanteric or high femoral shaft type of fracture, which is so difficult to control. Even in those rare fractures in which both the neck of the femur and the trochanteric region are involved, stability may be secured. While reduction and fixation of the lesser trochanter is not a necessity, it too can frequently be affixed by this apparatus. Where nailing is properly done no coxa vara or external rotation deformity will develop unless the nail breaks, bends or pulls out of the bone. The nail most frequently used is angled at 130 degrees and is of 3 inch (7.6 cm.) length.

To secure operative speed, and speed is essential, a surgical and roentgen team must work together. Mechanical details of reduction and nailing have been published elsewhere.

POSTOPERATIVE CARE

After operation patients are replaced temporarily in light traction pending application of a Thomas brace with pelvic band and knee lock. Continuance of such a brace until solid union is obtained is essential. Early full weight bearing with the brace is neither necessary nor advisable. Crutch ambulation with minimal weight bearing can rapidly be permitted. Union rarely occurs before three months and sometimes is not complete up to seven months. This can be clearly shown by progressive protrusion of the nail through the neck and head as time passes. Too early or active weightbearing can encourage this protrusion. Allowance must be made for the progressive protrusion by selection of a nail which is not too long. We would urge that early mobilization of the patient is admirable but early full weight bearing may prove disastrous.

One must continuously remain aware of the fact that these patients are old and afflicted with many debilitating factors aside from their fractures. They have been badly injured and need especial nursing attention and care. Fluids by infusion, high protein intake, close attention to skin pressure points, indwelling catheterization for incontinence, frequent change of bed linens, rapid cessation of sedation, cardiac investigation, consultation and medical care must all be carefully carried out.

COMPLICATIONS

There have been complications from this method of treatment but far less frequent and much less devastating than those found in the conservatively treated group. Four infections occurred, two of minor importance, while two were gas gangrene resulting fatally. The patients are aged and the tissues devitalized, and unless care is taken considerable muscle damage may be done. Pulmonary embolus occurred but twice among 95 patients, both times eventuating in death. The source of embolus in 1 case was proved by autopsy to be in the uninjured leg. Postoperative pneumonia occurred in 2 patients and was successfully treated. Nails broke in 3 instances and were replaced. In 4 instances the nail tore out of the bone, twice through the side of the head and neck of the femur and twice pulling the screws out of the shaft of the femur. In 2 of these the nail was replaced and in 2 others union was obtained though with some deformity. Early weight bearing against advice or refusal to wear the brace accounted for these mishaps. No cases of nonunion or aseptic necrosis of the head of the femur have occurred.

The most annoying complication has been that of overdrive. Gradual perforation of the nail through the head occurs until union takes place. If too long a nail is used in the first instance and closely approaches the cartilaginous surface of the head, gradual protrusion during healing and union may occur with perforation of the head by the nail and impingement against the acetabular margin. We had not expected this situation and discovered it by follow-up roentgenogram. Most of the patients were asymptomatic though with some limitation of motion and development of traumatic arthritic change in the acetabulum. Removal of such nails has been simple and without operative complications. Such protrusion has been most frequent in the intertrochanteric comminuted type of fracture.

Comparative Hospital Mortality.—Under conservative traction treatment there was a hospital mortality of 36 per cent. In the cases in which nailing was done there was a hospital mortality of only 12.6 per cent. Hence three times as many patients died during their hospital care under conservative treatment as did when open reduction and nailing was employed.

Comparative Development of Senile Psychosis.—Development of severe senile psychosis is apt to occur in patients of this age group. Such a complication is almost worse than death, since it divorces the patient permanently from his family and yet demands continuing expensive care and a debased and suffering existence. In 11 per cent of the patients treated by balanced traction such psychoses developed, and they were transferred permanently to mental institutions. Of the patients who were operated on and whose fractures were supported by internal fixation only 2.1 per cent experienced similar psychoses.

Other Complications.—Other complications such as incontinence, cystitis, pressure sores, stiff knees, permanent vascular changes, peroneal nerve palsies, muscle atrophy and permanent hip deformities were found to be decidedly reduced in the group treated surgically.

SURVIVAL

Considering the advanced age of these patients as a group, not many can survive for more than a few years regardless of mode of treatment. However, on reviewing the patients we found that of those treated by traction only 32 per cent survived one year from the date of fracture. Contrast this with the 72 per cent who survived one year treated by internal fixation. By the end of the second year only 29 per cent of the traction-treated patients were alive, while 38 per cent of those treated by internal fixation survived. At the end of four years only 13 per cent of the conservatively treated patients were alive, while 30 per cent of those in whom nailing was done survived.

HOSPITAL SECLUSION

A long hospitalization has many disadvantages. On humanitarian grounds one may disregard expense, but on factual grounds for a large group of patients no institution management does so. Regardless of the factor of expense, the patients themselves do not care for prolonged incarceration. Traction-treated patients remained an average of fourteen weeks, while those with internal fixation stayed but eight weeks. Even this eight weeks' stay was a kindness rather than a necessity. Clearance of bed facilities for other desperately needy patients was greatly improved by surgical treatment

SELECTION OF CASES

It is difficult to select the case in which one refuses to use nailing in view of our experience. We have refused operation twice in the past two years. In both instances the patients could undoubtedly have been given the benefit of internal fixation. We believed both moribund; yet one lived eight days and the other twelve days in traction. Responsibility of not operating on these elderly patients is serious. Clearly these 2 patients had sufficient vitality to have withstood operative procedure. Perhaps had we nailed their fractures they might have lived. Even if operation were merely the means of keeping the patient comfortable during terminal stages and free of painful complication, it would be justified. The same experience has been found in these patients with trochanteric fractures as was found in nailing fractured necks of the femur. Frequently the patients survive despite adverse preoperative opinion. We now operate on and nail all intertrochanteric fractures.

SUMMARY

Because of circumstances regarding the location of the patient, the experience of the surgeon, and the equipment available, conservative treatment of the trochanteric fracture may be necessary. The best conservative treatment we believe to be balanced Russell traction.

Internal fixation with the Jewett nail, an angled appliance, has reduced hospital mortality to one third and development of severe senile psychosis to one fifth of that sustained by patients treated in traction. All other complications are sharply reduced. It has produced a four year survival rate over twice that of conservatively treated patients while greatly improving the functional end results of the survivors.

Surgical reduction and fixation of trochanteric fractures with the angled nail is difficult and requires experience. Certain complications such as progressive protrusion of the nail and tissue necrosis may be avoided by advance knowledge of their occurrence and care in their prevention.

Two Categories of Teachers.--Thomas Lewis clearly foresaw such a danger and warned against it; but it is clear that the presence in the modern medical school of two categories of teacher, the practising consultant and the salaried academic teacher, opens the door to this disastrous dichotomy. The practising teacher is familiar in his everyday work with the individual seen against the backgrounds of his home, his family, and his work. The full tide of human needs and distresses bears down daily upon him, and the arts and techniques of medicine are his constant and exhausting preoccupation. He may cease to look beyond them.

For the cloistered academic teacher life is different. He gets his patients washed and tidied and laid out in rows in hospital wards; their importunate and exacting wives and mothers-in-law do not intrude upon his profound cogitations. No unpleasant smells or noises break in on his ordered eloquence; house-physicians and nurses wait on his bidding and tremble at his voice, and all those seeming irrelevances that are so necessary to the balanced comprehension of the patient's total situation are carefully tidied away out of his sight. He does not miss them, for he has never known them. He is rather like the florist who can arrange the plucked blooms, from which the dead leaves and the dirty roots have been removed and the earwigs shaken off, into all the combinations of form and colour his fancy dictates.--Walshe, F. M. R.; Teachers of Medicine, *Lancet* 2:817 (Dec. 6) 1947.

MEDICAL MANAGEMENT OF THE PATIENT WITH A FRACTURE OF THE HIP

R. H. FREYBERG, M.D. and M. D. LEVY JR., M.D.
New York

Except in rare instances when younger persons receive severe and unusual trauma such as would occur in automobile accidents and the like, persons who sustain a fracture of the hip are adults in the older age group. The general medical management of these patients therefore resolves itself largely into a problem of geriatrics. To determine the incidence and the nature of the more common medical problems and complications encountered analysis has been made of all cases of fracture of the hip treated in the Hospital for Special Surgery during ten years ending December 1946.

Seventy-two per cent of the patients were women (table 1); the largest incidence occurred between 70 and 80 years. The average age of the women was 66 years, ten years older than the average age of the men and three years older than the general average. The differences in age between sexes is clearly shown in table 1. This appears to be because men are apt to sustain severe trauma in the course of their work at a younger age than the women, who usually fall about the house or in the street.

TABLE 1.—*Age Incidence of Patients With Hip Fractures*

Cases		Years 20-29	30-39	40-49	50-59	60-69	70-79	80-89	90-99	Average Age
Male	47	2	6	7	11	11	5	5	0	56
Female	121	2	4	7	19	29	42	16	2	66
Total	168	4	10	14	30	40	47	21	2	63

Many patients were obese women in the postmenopause period. Significant osteoporosis was frequent and is undoubtedly important in the etiology of fracture. Most of these patients reported a "fall and fracture" One wonders whether in some instances the fracture may have occurred first and caused the fall. No doubt in most of the cases fall caused the fracture in bone greatly weakened by osteoporosis and with the added trauma of obesity which normal bone would ordinarily withstand.

Significant complications occurred in 17 per cent of all cases (table 2). No complications were encountered in patients under 40 years of age. The patients in all but 1 complicated case were more than 50 years old; the average age was 71 years. Again, the average age of the women was ten years older than that of the men. Fatal

TABLE 2.—*Age Incidence of Common Complications in Patients With Hip Fracture*

Cases	Total	Years 40-49	50-59	60-69	70-79	80-89	90-99
Diabetes	6		1	1	2	2(2)	
Decubitus	4		2		2(1)		
Pneumonia	7			2(2)	1(1)	3(2)	1(1)
Hypertension	6			2	4		
Pulmonary Embolism	4	1	2(1)	1(1)			

Total cases with complications: 29; average age: 71
Male: 7; average age: 64
Female: 22; average age: 74

Read in a panel discussion on Fractures of the Upper End of the Femur before the Section on Orthopedic Surgery at the Ninety-sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1947

From the Medical Service, Hospital for Special Surgery, New York cases are shown in parentheses; all but 1 were in patients past 60 years. Note that 6 of the 7 patients with pneumonia and 2 of the 4 patients with pulmonary infarction died.

The incidence of arteriosclerosis is not statistically analyzed because frequently no comment was made concerning sclerotic arteries, although such must have existed in most of the patients past 60 years of age. Arteriosclerosis was diagnosed usually only when it was considered responsible for some other illness. Also, the incidence of obesity could not be accurately determined, for this diagnosis was made only when it was rather severe.

Common preexisting complications were obesity, diabetes mellitus, hypertensive vascular disease and arteriosclerotic·heart disease (table 3). None of these illnesses appeared to endanger the patient or cause death, but may make management of the patient difficult should infection or vascular accident occur. Diagnosis of renal and hepatic·disease was not encountered among the cases analyzed.

TABLE 3.—*Preexisting Complications in Patients With Hip Fracture*

	Number	Percentage
Obesity	10	6.0
Diabetes	6	3.6
Hypertension	6	3.6
Arteriosclerotic heart disease	5	3.0
General arteriosclerosis and senility	3	1.8
Paget's disease (bone)	1	0.6

The most important complications were those acute illnesses which occurred after the fracture (table 4). These were chiefly pneumonia, decubitus ulcers, phlebothrombosis and pulmonary embolism. It is significant that most of the cases of pneumonia and pulmonary embolism occurred in patients confined to bed.

TABLE 4.—*Complications Following Hip Fracture*

	Number	Percentage
Pneumonia*	7	4.2
Decubitus ulcer	4	2.4
Pulmonary embolism†	4	2.4
Thrombophlebitis	2	1.2
Inanition	2	1.2
Cerebral hemorrhage (traumatic)	1	0.6
Hypertensive encephalopathy	1	0.6
Anemia	1	0.6
Pulmonary embolism or coronary occlusion	1	0.6

*Four patients were bed patients at onset of infection; 1 in a wheel chair four days; 1 in wheel chair ten days.

†Three patients were treated in bed; 1 in wheel chair four days before embolism occurred.

The over-all mortality rate was 7.2 per cent (table 5). The average age in fatal cases was 74.5 years; 67 per cent of the deaths were in women. Fifty per cent of all deaths were due to pneumonia in patients more than 60 years of age (1 was 95 years) One patient became ill on the fourth postoperative day, 2 during the fourth week and 3 during the third and fourth month after fracture. Most infections began in bed patients or in those who had just begun wheelchair activity. In these 6 fatal cases of pneumonia there was arteriosclerotic heart disease in 2, decubitus ulcers in 2, and in 1 hypertension, decubitus and arteriosclerotic heart disease occurred. Both fatal cases of pulmonary embolism were in bed patients; 1 occurred on the sixth day, and 1 on the eighth day after fracture.

When the various complications are tabulated in correlation with one another (table 6) it is noted that frequently obesity, diabetes, hypertension and arteriosclerosis coexisted in the same patient. The lethal complications (pneumonia and embolism) in about 50 per cent of the cases were associated with arteriosclerosis or hypertension.

TREATMENT OF COMPLICATIONS

Prevention of obesity would undoubtedly lower the incidence of hip fracture, another of the many reasons for maintenance of normal weight during aging. Weight reduction should be started in all obese patients, if not before, at the outset of treatment for the fracture. In these older persons whose activity is sharply curtailed because of the fracture transformation of energy is small, frequently 1,500 to 1,600 calories per twenty-four hours; so in order to accomplish satisfactory weight reduction, the diet should provide 800 calories or less during each twenty-four hour period. It should contain 60 to 80 Gm. of protein and enough bulk to be satiating by liberal use of low carbohydrate vegetables and fruits.

It should be clearly understood that osteoporosis is not primarily a disturbance of calcium and phosphorus metabolism; it is the insufficient production of osteoid tissue. Most common causes are: (1) failure of stimulation of osteoblasts due to postclimacteric deficiency of steroid hormones; (2) decrease in stimulation of osteoblasts due to reduced physical activity (disease atrophy); (3) protein deficiency which depletes the bone matrix, and (4) old age atrophy of bone matrix.[1] If the frequency of the commonest of all types of osteoporosis, postmenopausal osteoporosis, and the many fractures directly due to it were better known there surely would be better prophylaxis. Postclimacteric persons should be particularly careful to insure a generous intake of protein, calcium and phosphorus. If roentgenograms revealed significant osteoporosis treatment should be instituted according to the plan recommended by Reifenstein and Albright,[1] using adequate amounts of estrogens or androgens. Of the former, doses of 0.5 to 1 mg. of diethylstilbestrol orally daily; 2.5 to 3.75 mg. estrone sulfate or 1.6 to 3.3 mg. estradiol benzoate two to three times weekly for two or three weeks then 5 mg. weekly for four to six weeks, and then rest one to two weeks will usually be helpful. Of the male hormone, 10 to 20 mg. testosterone arally and 20 to 25 mg. intramuscularly weekly for one to two months is good. Such a series may be repeated several times. One to two 75 mg. pellets of testosterone may be implanted every four months. When used, male sex hormones, should be given for at least two or three months. Retention of nitrogen and calcium, production of osteoid tissue and calcification of bone result, but benefit is notoriously slow. Treatment may be needed for many months. The value of prophylaxis should be emphasized.

Prolonged rest quietly in bed should be avoided whenever possible, for Deitrick and associates[2] and others have shown that this aug-

ments excretion of calcium and causes osteoporosis.

The treatment of hypertension and arteriosclerosis in a patient with fracture can only be ameliorative. Measures to reassure and quiet the patient are important: the wise use of sedatives is advised. Phenobarbitol in doses of 16 to 32 mg. two or three times daily is usually beneficial: combinations with vasodilators (such as mannitol hexanitrate) are popular but of limited value. In our cases these lesions had no effect or only minor influence on the course of the patient with fracture of the hip. However, severe arteriosclerosis may embarrass the course of the elderly patient; the general decline and death of some elderly persons with fracture must depend directly on advanced generalized vascular disease for which treatment is inadequate. The status of the heart and circulation should be determined promptly in all persons suffering fracture of the hip, and early correction of cardiac decompensation, if it exists, should be accomplished.

Diabetes mellitus is usually mild and easily managed in older persons and, as shown in the cases analyzed, it need not be hazardous in the patient with fracture of the hip. Proper diet and insulin, when needed, will control this disease so that it will not delay convalescence. It was pointed out by Newburgh[3] that in the older obese persons so-called diabetes is frequently due to fatty liver and the only treatment needed is a suitable reduction diet.

Table 5.—*Deaths in Patients With Hip Fracture**

Immediate Cause of Death	Age	Sex	Type of Fracture	Treatment	Onset, Days After Fracture	Onset, Days After Operation	Activity	Other Illness
Pneumonia	74	F	Intertrochanteric	Closed, plaster	71		Chair 4 days	
Pneumonia	81	F	Intertrochanteric	Traction, Closed	76		Chair 8 days	
Pneumonia	60	M	Intertrochanteric	Shanz osteotomy	139	90	Bed	Arteriosclerotic heart disease
Pneumonia	95	F	Neck	Lippman screw	9	4	Bed	
Pneumonia	87	M	Intertrochanteric	Closed, plaster	22		Bed	
Pneumonia	68	F	Neck	Smith-Petersen nail	25	23	Chair 21 days	Thrombophlebitis, decubitus, hypertensive arteriosclerotic heart disease
Pulmonary embolism	50	M	Neck	Closed, plaster	8		Bed	
Pulmonary embolism	65	F	Neck	Closed, splint	6		Bed	Obesity
Inanition†	74	F	Intertrochanteric	Blade, plate			Bed	Decubitus; arteriosclerotic heart disease
Inanition‡	80	F	Neck	Smith-Petersen nail			Bed	Diabetes; arteriosclerotic heart disease
Cerebal hemorrhage, traumatic	77	F	Neck	Smith-Petersen nail	10	9	Bed	
Anemia?§	83	M	Neck	Smith-Petersen nail			Chair 26 days	Obesity; diabetes

*The mortality rate was 7.2 per cent; the average age, 74.5.
†Death occurred fifty-four days after the fracture and forty-six days after the operation.
‡Death occurred eighty-four days after the fracture and eighty-one days after the operation.
§Death occurred thirty-eight days after the fracture and twenty-six days after the operation.

Table 6.—*Correlation of Common Complications of Hip Fracture*

		Diabetes	High Blood Pressure	General Arteriosclerosis	Arteriosclerotic Heart Disease	Obesity	Decubitus Ulcer	Pneumonia	Thrombophlebitis	Pulmonary Embolism	Only Disease
Diabetes	6			1	1	5					
High blood pressure	6			1	2	3		1	2

Obesity	10	5	3	2			2		1	1	
Decuitus	4	1	1		1	2		1		1	
Pneumonia	7		1		3				1		4
Thrombophlebitis	2		2		1	1		1			
Pulmonary embolism	4					1	1				2

Most fatalities among the cases reviewed were due to pneumonia—50 per cent. However, penicillin became available only at the end of the period of this study; and sulfonamide compounds were available for only some cases. With antibiotic therapy now available some of these fatalities would not have occurred. It seems wise to employ prophylactic antibiotic therapy for seven to ten days after fracture or surgical treatment. Penicillin, 200,000 units orally twice daily, will usually be sufficient; protection would certainly result from 100,000 units of crystalline penicillin intramuscularly each twelve hours. Such could have prevented death in only 1 of our 6 fatal cases, for 5 patients contracted their infection twenty-four to ninety-six days after fracture, which seems too long a time to continue prophylactic antibiotic therapy. Prompt use of peni-

cillin when coccic pneumonia develops should greatly reduce mortality.

The second most frequent postfracture complication was phlebothrombosis, which in some cases produced pulmonary embolism and infarction. Two deaths were on this basis. Pulmonary infarcts were not more frequent in the patients treated with open surgery but were more frequent in patients who were confined to bed. The longest time after fracture that lethal infarcts occurred was eight days. Anticoagulants were not employed in our cases. Allen[4] has emphasized the postoperative value of "dicumarol" to prevent the occurrence and extension of venous thrombosis; calculation based on his statistics indicates that proper use of "dicumarol" in our cases could be expected to prevent both deaths which occurred from pulmonary infarction. It appears therefore that anticoagulants should be used prophylactically during the first ten to fourteen days after fracture of the hip, especially in bed patients, and certainly in all cases of pulmonary embolism to prevent extension of the phlebothrombosis and recurrent fatal embolism. The only danger in using anticoagulants is hemorrhage, and this is far less hazardous than is thrombosis and embolism. Hemorrhage can be prevented by proper control of coagulation time by laboratory guides. Anticoagulants should not be used without proper laboratory facilities. Vitamin K is a dependable antidote for excessive "dicumarol" effect.

Other important prophylactic measures against phlebothrombosis include leg exercises for those patients who need continued bed rest. An oscillating bed may be of distinct value if treatment for the fracture will allow its use. It is desirable to avoid long therapeutic bed rest in older patients; for this reason the nailing procedure and early ambulation are advantageous. In cases of identifiable leg vein thrombosis, in which anticoagulants are not employed, ligation and thrombectomy may be beneficial.

IMMEDIATE CARE OF THE PATIENT WITH A FRACTURE

Good nutrition is important for wound healing and for the patient's general health. The caloric value of the diet should be adjusted as indicated by the body weight: Obesity should be reduced, and the undernourished patient should have a high caloric diet. Adequate protein intake should be insured. There is now ample evidence[5] that the gastrointestinal tract of elderly persons can handle average or slightly high protein food mixtures well. Good protein hydrolysates and amino acid mixtures are now available if protein supplements are needed. It is well to give food orally whenever possible; parenteral feeding should be used only in patients who cannot eat or retain sufficient food. The only indication for a low protein intake is pronounced renal functional impairment; then the twenty-four hourly intake may need be sharply curtailed to help prevent renal failure.

Adequate vitamins should be used to prevent or correct a deficiency state. B complex and ascorbic acid are the most important vitamins and can be supplied by use of a good multivitamin capsule with 100 or 200 mg. of ascorbic acid added daily. Vitamin B complex may be helpful for anorexia. Most patients will absorb orally administered vitamins adequately, but with intestinal disease and for a short while after the operation the parenteral administration of vitamin B and C may be necessary or helpful.

Associated illnesses should be recognized and appropriately treated. The patient with arteriosclerosis or hypertension should receive special attention to prevent or correct a failing heart which may result from the embarrassment of the trauma or surgical treatment. Appropriate treatment for anemia should be instituted from the outset. Catharsis may be required for bed patients. Nervous and apprehensive patients will be helped by small doses of sedatives administered through the day; adequate sleep should be insured at night time, but generally the elderly patient requires small doses of sedatives. They should be discontinued when no longer needed.

SUMMARY

The medical care of the patient with hip fracture resolves itself into good management of an elderly, traumatized patient who may need surgical treatment. It is best provided by the close cooperation of an internist and the surgeon. Preexisting conditions seldom are important factors in survival but commonly affect the speed of convalescence. Tissue senility, degenerative and arteriosclerotic changes account for the fact that in the patients with a fractured hip the tissues have less resistance and reserve. Vigilant attention should provide best possible function of vital organs, good nutrition and proper treatment of coexisting diseases and complications. The most dangerous complications are pneumonia and phlebothrombosis with pulmonary embolism. There are now effective prophylactic measures against such complications which should be wisely employed.

The survival rate in the cases analyzed certainly indicates the improved care for patients with hip fractures due largely to improved anesthetics, better preoperative and postoperative care, greater surgical skill and improved technic. More vigilant medical care including the proper prophylactic and therapeutic use of antibiotics and anticoagulants will certainly further improve the convalescence of patients with fracture of the hip and will further increase their survival.

ASEPTIC NECROSIS OF THE FEMORAL HEAD FOLLOWING FRACTURE OF THE HIP

CARL E. BADGLEY, M.D.
and
R. H. DENHAM, M.D.
Ann Arbor, Mich.

The term "aseptic necrosis" has been applied somewhat loosely to designate vascular death of the head of the femur in certain fractures of the neck of the femur, traumatic dislocations of the hip and displacement of the upper femoral epiphysis. Similarly the term has been employed with the epiphysial changes seen in conditions such as Legge-Calvé disease.

It is essential to define what is meant by aseptic necrosis. It is clear in reviewing the literature that there are various concepts of the significance of the term which lead to ambiguity in diagnosis and studies on end results. Boyd's[1] recent report of complications of fractures of the neck of the femur illustrates his difficulty in differentiation of degenerative arthritis and aseptic necrosis. In our study, we have been confused as to when we could say this is definitely aseptic necrosis with arthritic changes or this is degenerative arthritis. If we regard any degenerative change in the head as resultant from aseptic necrosis, then we become confused in the changes noted in the hip joint after extensive fracture dislocations of the hip. Similar lesions are produced elsewhere in other joints by a process defined as traumatic arthritis.

[1] Boyd, H. B., and George, I. L.: Complications of Fractures of the Neck of the Femur, J. Bone & Joint Surg. 29:13-18 (Jan.) 1947.

The term "avascular necrosis" has been used for this entity and might be limited definitely to a generic term denoting essentially a dead head. Reparative processes make it possible to revivify the dead head with various end results, such as (1) degenerative arthritis, (2) a partial regeneration of the head with collapse of the superior weight-bearing surface of the head and (3) occasionally a regenerated normal-appearing head. "Avascular necrosis" then could well be utilized as the generic name for the entity denoting the static state, with the term "aseptic necrosis" used to denote the process of repair, a dynamic time period in which transformation of the dead or partially dead head has incompletely occurred, allowing the potential of collapse of the remaining untransformed portion of the head or lastly producing without collapse a degenerative arthritis, a descriptive term for the cartilage changes, necrosis and loss of joint space.

Avascular necrosis may, then, be defined as death to part or the whole of the head of the femur due to vascular damage primarily of the posterior and anterior circumflex femoral vessels. The vascular supply from the ligamentum teres may or may not be injured similarly. When avascular damage has been sufficient to produce necrosis, the deprivation of blood supply is immediate and the death of the bone tissue occurs in a matter of hours. The evidence clinically of death of the fragment is not manifest, however, by our best diagnostic methods roentgenologically until between the second and third month of the fracture. Density is the chief diagnostic feature, contrasting the atrophy of the distal fragment with the unabsorbed fragment of the head.

Not all fractures of the neck of the femur produce avascular necrosis. Watson-Jones[2] stated that subcapital fractures if above the site of the vascular entry inevitably, transcervical fractures frequently and basal fractures never undergo avascular necrosis.

Inasmuch as the diagnosis of avascular necrosis cannot be made clinically before the end of the second month, it is wise to regard all fractures of the neck of the femur of the subcapital type or the transcervical as potentially leading to avascular necrosis. Watson-Jones[2] stated that if avascular necrosis arises the result is a failure, but if avascular necrosis is avoided the result should be a brilliant success. His chief point here is well taken primarily, that avascular necrosis might not be the result of the original injury but can be produced by vascular damage from manipulation or by open reductions, cutting the capsule and further interfering with the blood supply.

The frequency of avascular necrosis following fractures of the neck of the femur treated by internal fixation and resulting in bony union is distressingly high. The report of a study made by the Academy of Orthopaedic Surgeons gave an incidence of approximately 40 per cent. Boyd's[1] figures are confusing but he stated in one chart that aseptic necrosis occurred in 33.6 per cent and arthritis in 33.6 per cent, which would give an aggregate of degenerative processes in 67 per cent of the healed fractures of the neck. Lawson Thornton[3] estimated that 50 per cent of the traumatic dislocations of the hip show later degenerative change. In our[4] cases of operative reduction of displaced upper femoral epiphysis the incidence of aseptic necrosis was only 4 per cent but the incidence of arthritis was 28 per cent, which again, combined in one figure, would express a degenerative process secondary to an avascular necrosis which would be significant, yet, again, degenerative arthritis in the untreated case of upper femoral displacement is the rule without evidence of avascular necrosis. This stresses the importance of defining the clinical entities seen as complications.

Brailsford[5] stated that he had not seen avascular necrosis result from external fixation. We have 5 such cases in this study; treatment by plaster spica cast was followed by bony union of the neck. We agree with Watson-Jones that the internal fixation in itself does not produce avascular necrosis. It does, however, produce a much higher group of cases in which bony union occurs even though a dead head was present, and the process of transformation of the dead head to a living head may be incomplete so as to produce collapse of the upper portion of the head as is seen in aseptic necrosis or to produce degenerative arthritis of the hip from necrotic cartilaginous changes.

CLINICAL ENTITIES COMPLICATING FRACTURES OF FEMORAL NECK

There are four main types of complications noted in the process of repair of fractures of the neck of the femur: 1. Bony union of the fracture may be followed after a period of functional use by pain, progressive loss of function with roentgen changes of varied densities in the head associated with loss of contour of the head from collapse of the superior weight-bearing surface of the head. This process we should like to term "aseptic necrosis," and we should like to confine this term to this specific lesion. 2. Bony union of the fracture may be associated with a period of function of the hip followed by pain and progressive loss of function associated with roentgen evidence of diminished joint space, normal contour of the head, areas of varying densities throughout the head and acetabular changes akin to arthritic changes. The term "degenerative arthritis" properly can be applied to this group of cases. 3. Nonunion of the fracture may be associated with a dead head. The hip has never functioned satisfactorily, and bony union has not occurred. Roentgenograms show the evidence of nonunion, and the head is dense in contrast to the distal fragment, denoting a dead head. Operative therapy for union might be successful, but the first or second complication might result later. 4. Nonunion of the fracture may be associated with a vital head. Here atrophy has occurred similarly in both fragments. The head is viable. Operative aims for union may well lead to success in healing without later degeneration of the head.

For many years Phemister[6] has consistently added to our knowledge of the pathology of these complications. From his first paper in 1920, on "Recognition of Dead Bone Based on Pathological and X-Ray Studies," to his last paper with Dr. Sherman, in 1947, there has been a clarification of the pathologic processes which produce these complications of fractures of the neck of the femur. We can best state the facts which he has substantiated by clinical and pathologic studies: 1. Union can occur in the presence of avascular necrosis.[6b] 2. Pathologic changes in the hip joint are rare if the head is alive, but are constant and may become severe if the femoral head is dead[6]. 3. Survival of the femoral head from the fracture depends on how much blood supply was damaged. There is no evidence that death of the head occurs long after the fracture when union has failed. 4. Circulation of the head occurs through the anterior and posterior circumflex vessels which lie in that portion of the capsule reflected on the neck and more especially in the posterior portion of the capsule. 5. If the posterior portion of the capsule remains intact, vascular supply may be sufficient. (Our findings of free blood in the posterior gluteal bursa may have significance as a diagnostic sign of vascular damage.) 6. If the head remains viable, but nonunion occurs, the principal change is disuse atrophy equal in both fragments. This nonunion head never collapses and the cartilage is well preserved. Operative procedures to produce union are usually successful and degenerative arthritis does not follow. 7. In a dead head from interference with blood supply, atrophy of disuse cannot occur. 8. The process of transformation of the dead head has been well described by Phemister and Sherman.[6c] It should suffice here to say that creeping substitution from the distal fragment with increased vascularity from the lower fragment and also from the ligamentum teres vessels is the chief process of repair. 9. Depression of the unaltered weight-bearing portion of head is indicative of beginning collapse of the untransformed portion of necrotic head. 10. A new fracture line passes through the zone of invasion and of replacement of dead bone by living bone. The invading front consists of connective tissue and blood vessels replacing dead marrow and some absorption of trabeculae replaced partially by spongy new bone. 11. Pathologic fracture at the junction of dead and living bone from prolonged weight bearing is common in aseptic necrosis. 12. Degenerative arthritis is regularly present in long-standing cases of necrosis of the head with nonunion, but rarely as severe as in old cases of necrosis of the head with body union. 13. When there is nonunion of the fracture, there is usually no collapse of the necrotic head, but if the fracture unites in the presence of a dead head and weight is borne, collapse of the partially replaced head is to be expected. 14. Operation on an ununited fracture of the neck with a dead head may result in bony union. Transformation may occur, but degenerative arthritis may develop later.

PREVENTION AND TREATMENT OF AVASCULAR NECROSIS

Care to prevent further trauma to the fractured hip should be observed. Vascular damage may result from rough handling in transport. Manipulative reduction should be carefully done to avoid damage. For years we have not manipulated fractures of the neck of the femur except in rare cases. Skeletal traction through the lower part of the tibia and fibula with Russell traction principle has satisfactorily reduced most of the fractures. If manipulation is required, usually a modification of the Leadbetter method is employed. Reduction can be accomplished immediately by traction, and, when the patient's condition warrants, early internal fixation should be obtained. At one time, a study of our statistics showed 90 per cent bony union in patients treated immediately by traction with internal fixation within forty-eight hours in contrast to 65 per cent bony union after a delay of two weeks prior to fixation.[8] The intervening capsule becomes adherent to the fracture site and interferes with closed reduction and healing unless treated early so that the capture can be freed from the bone ends.

Open operation should be avoided if possible. Incision through the capsule can interfere with the anterior circumflex vessels and do further vascular damage to the head of the femur. Certain fractures, however, which cannot be satisfactorily reduced are better treated by open operation and reduction accurately obtained under inspection. We have found unusual types of fractures, not described hitherto to our knowledge, which would have made closed reduction impossible. The cortex of the neck has remained intact in a few cases with the endosteal portion pulled out like a watermelon plug and remaining with the head fragment. Again, the reverse has happened, with a portion of the neck pulled out of the head fragment and with the cortex remaining on the head fragment, preventing reduction. The oblique fractures with a long fragment remaining on the inferior surface of the head fragment particularly are apt to be displaced on nailing unless open reduction is performed. Accurate reduction is essential to coaptate fresh fracture surfaces even though open reduction is required to achieve this.

Traction in bed for some time following nailing prevents displacing the nail. In some cases, adduction of the hip alone can displace the nail from the atrophic head in the elderly patient. We advise, if the patient can tolerate it, at least six weeks of continuation of skeletal Russell traction, which allows mobility of the hip and knee and relative freedom in bed.

Avoidance of weight bearing on the injured hip is insisted on for a minimum of six months in all cases. If at the end of two to three months routine roentgen check-up shows increased density of the head, particular emphasis is placed on avoidance of weight bearing and protection until transformation of the head is complete.

Transformation of the head to viable bone covered with functional cartilage may result even in the cases of avascular necrosis, if sufficient time is given without weight bearing for complete regeneration of the head. Collapse and degenerative arthritis are practically certain to result unless recognition is made of avascular necrosis between the second and third month after the trauma and avoidance of weight bearing is continued until the avascular head is completely revived.

Wise[9] has shown in his study of the autopsied specimen of a recently nailed hip that death of the head does not necessarily occur in a transcervical fracture and more important, defended internal fixation by the fact that the "vitallium" nail in itself is a factor in bringing new blood supply to the head along the tract of the nail.

In conclusion, avascular necrosis of the head of the femur following fracture may eventuate in (1) occasionally complete retransformation of the head to vital functioning structure; (2) aseptic necrosis characterized by a partial transformation of the head by creeping substitution with, however, collapse and fracture of the weight-bearing portion of the head at the junction of the advancing zone of repair; this complication might be avoided by recognition of the avascularity of the head between the second and third month by roentgen evidence of increased density of the head and then by protecting against weight bearing until transformation is complete; (3) degenerative arthritis characterized by loss of joint space due to necrotic cartilage; collapse of the head does not occur; this may be a complication from avascular necrosis which cannot be prevented; (4) nonunion; either a dead or a live head may result after fractures of the neck of the femur; this complication occurs with minimal frequency if satisfactory internal fixation is employed.

In spite of careful treatment, avascular necrosis is a serious complication of fractures of the neck of the femur which may result in a painful, poorly functioning hip of the aseptic necrosis or degenerative arthritis type.

SELECTION OF OPERATIVE THERAPY

The selection of operative therapy for these complications depends on the type of patient, the extent of the degeneration and the therapeutic choice of the surgeon.

Arthroplasty of the "vitallium" mold type has been successfully utilized by Smith-Petersen[10] and his associates in 42 cases with 85 per cent satisfactory results to the patient and to the surgeon. They employed the routine mold arthroplasty if minimal aseptic necrosis was present; a modified Whitman reconstruction operation if aseptic necrosis involved a large part of the head, removing the head and covering the trochanter with a "vitallium" mold; a modified Colonna reconstruction in nonunion with absorption of the neck, applying a "vitallium" mold and deepening the acetabulum.

Badgley[10] reported 3 excellent, 2 good and 2 fair results out of 9 cases with aseptic necrosis treated by "vitallium" cup arthroplasty.

The Mayo Clinic reported[11] that the results from arthroplasty for aseptic necrosis of the hip were disappointing. In more than half of their cases, results were poor.

The Colonna reconstruction operation[12] has been successfully employed. In our experience this is a far better procedure than arthrodesis of the hip, allowing stability and painless motion of some functional extent. Recently Wilson[13] has added a "vitallium" mold to a Whitman type of reconstruction.

Exponents of hip arthrodesis, however, feel that successful arthrodesis can be produced in this group with high frequency, particularly with the addition of the three-flanged nail fixation. Haggart[14] reported 22 successful results in degenerative arthritis out of 24 cases. Freiberg[15] has successfully fused several such hips by the method of Brittain.

Recently Venable and Stuck,[16] 1946, have reported a muscle flap transplant for the relief of painful aseptic necrosis of the hip. This concept of reestablishing blood supply by a muscle flap transplant is a courageous attempt to fight the ill effects of avascular necrosis which may prove to be of distinct value. They reported 27 cases in which this method was used, with striking relief of pain in all but 1 case. Time and experience only will prove the success or failure of this procedure.

FRACTURES OF THE HIP

Results Following Treatment

H. B. BOYD, M.D. and I. L. GEORGE, M.D.
Memphis, Tenn.

Fractures about the hip joint may be seen in children and young adults but are injuries usually involving the aged. Approximately 80 per cent of these fractures occur in patients over 60 years of age. The fractures can be divided into two general classes—those involving the trochanteric region and those involving the neck of the femur. Both groups may be further divided into subclasses. These two types of fractures have several common characteristics. Each occurs in elderly persons, and both are more common in women (80 to 85 per cent) than in men. This is probably due to fact that women have a slightly wider pelvis with a tendency to coxa vara; they are usually less active and more prone to senile osteoporosis, and the life expectancy of a woman aged 60 is five years greater than that of a man.

Although the fractures are similar in some respects, they differ widely as to treatment and end results. The prognosis in the two fractures is entirely different in that nonunion is rarely seen in trochanteric fractures. This is due to several factors: The fractures of the neck involve a constricted area in the femur in which there is comparatively little cancellous bone; the periosteum of the neck of the femur is thin in elderly persons and there is no cambium layer.[1] The blood supply to the distal fragment is usually adequate, but

From the Campbell Clinic.

[1] Sherman, M. S., and Phemister, D. B.: The Pathology of Ununited Fractures of the Neck of the Femur, J. Bone & Joint Surg. 29:19-40 (Jan.) 1947.

the blood supply to the proximal fragment may be impaired or absent. In trochanteric fractures, a wide area of bone is involved, the major portion of which is cancellous, and both fragments have an adequate blood supply. As a result of impairment in blood supply, aseptic necrosis of the head of the femur and late degenerative changes of the femoral head are often seen after fractures of the neck of the femur. These complications have not been seen after trochanteric fractures. In trochanteric fractures, the surgeon may anticipate union in fair position if a method of treatment is employed that will prevent coxa vara. Our mortality rate (13. per cent) is higher in trochanteric fractures for three reasons: The average patient is slightly older (approximately two and one-half years); more trauma is required to produce the fracture, and if operative treatment is employed the operation is more extensive than that used in fractures of the neck of the femur. The chief problem in trochanteric fractures is to keep the mortality as low as possible by adequate medical and surgical treatment. To accomplish this, we prefer internal fixation. In the majority of cases, a Neufeld nail is employed. With successful internal fixation, the patient is allowed to sit up in bed or turn, or may be put in a wheel chair. Cleveland and co-workers[2] have estimated that the percentage of senile psychosis in elderly persons with trochanteric fractures is five times greater in those treated in body casts than in those treated by internal fixation. The mortality is less with internal fixation than with immobilization by means of a cast.

Fracture of the neck of the femur has been called "the unsolved fracture." In view of the present statistical studies, this should probably be changed to "the partially solved fracture." A year ago we studied and reported 300 complete, central fractures of the neck of the femur that had been nailed for one year or longer. Impacted fractures of the neck of the femur and pertrochanteric fractures were excluded. Only Pauwel's[3] type 2 and 3 fractures were included in the study. A report on these cases was made at the American Orthopedic Association.[4] Since that time we have added 60 additional hips, so that the present statistics are based on a series of 360 hips.

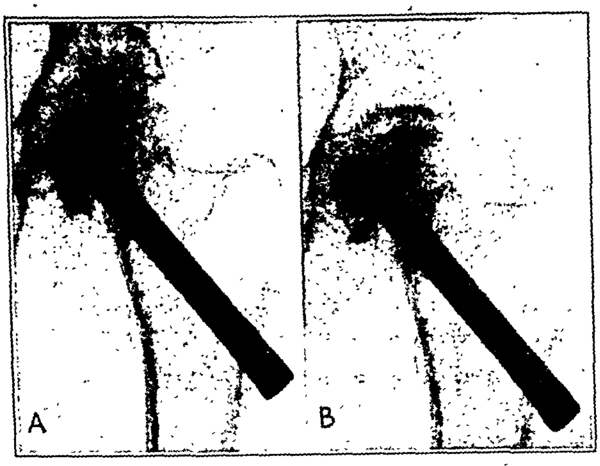

Fig. 1. A, 1 plus "arthritic changes" noted two and one-half years after nailing of a complete central fracture of the neck of the femur.
B, same hip six months later, showing 2 plus "arthritic changes."

MORTALITY

In calculating the mortality in the series previously reported, we included the known deaths up to six months following the operation. There has been some criticism regarding this method of calculating mortality. It is true that death may occur less than four weeks following the operation and still probably not be an operative mortality. Conversely, an operative mortality may occasionally occur more than four weeks after operation. In compiling statistics for this paper, all deaths have been included which occurred within four weeks of the operation. The over-all mortality is 7 per cent. Table 1 indicates the mortality for the various age groups. From the statistics seen in this table, it is noted that the prognosis as far as mortality is concerned is excellent for patients below 69 years of age. In patients 70 or above, the mortality rapidly rises by decades from 8 per cent to practically 43 per cent in the tenth decade.

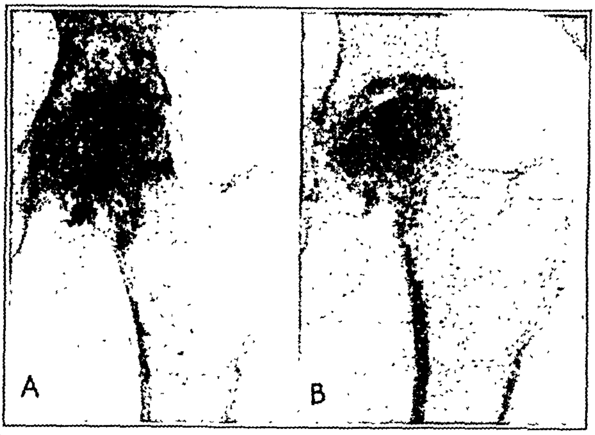

Fig. 2.—A, same hip as in figure 1 three years and three months following operation, showing 3 plus "arthritic changes."
B, same hip four years following operation, illustrating 4 plus "arthritic changes."

Table 1.—*Mortality in Fractures of the Neck of the Femur*

Age, Years	Hips	Deaths	Mortality, Percentage
Under 40	15	0	0
40-59	66	0	0
60-69	100	1	1.0
70-79	111	9	8.0
80-89	61	12	19.7
90-98	7	3	42.9
Total	360	25	7.0

The entire 360 hips were followed for a long enough period to determine the mortality. One hundred and fifty-eight hips, or 43.9 per cent, were followed less

Table 2.—*Fractures of the Neck of the Femur, Follow-up Study*

	Hips	Percentage
Follow-up less than 1 year	158	43.9
Follow-up over 1 year	177	49.1
Deaths	25	7.0
Total	360	100.0

than one year. Follow-up studies were available on 177, or 49.1 per cent, of the hips for a one year period or longer. These statistics are shown in table 2.

PERCENTAGE OF BONY UNION

The percentage of bony union was determined on the patients followed one year or longer. In some of the patients, especially those in the lower age groups, one may occasionally see an unquestionable bony union in less than one year. On the other hand, in some cases bony union occurs after a year, especially in patients that have gradual absorption of the neck of the femur. Table 3 shows the percentage of bony union and nonunion. In 177 cases there were approximately 85 per cent bony union and approximately 15 per cent nonunion.

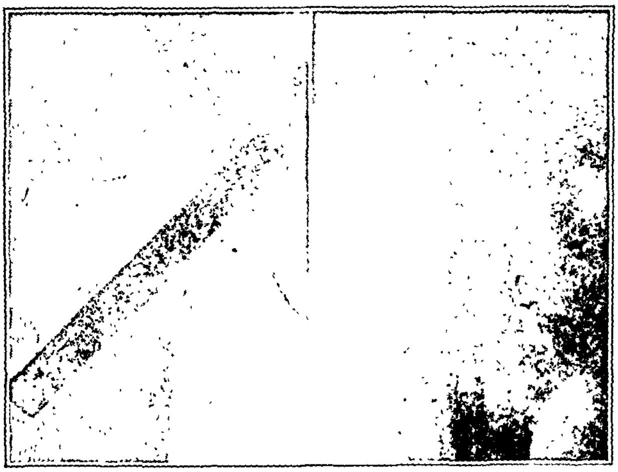

Fig. 3—Acute complete central fracture of the neck of the femur immediately after reduction and internal fixation with Smith-Petersen nail.

Table 3.—*Fractures of the Neck of the Femur, Bony Union*

	Hips	Percentage
Union	150	84.7
Nonunion	27	15.3
Total	177	100.0

Of the 150 hips that obtained union, 15, or 10 per cent, showed absorption of the neck of the femur to the extent of 1 cm. or more. This indicates that absorption of the neck in itself does not preclude union provided that the nail gradually extrudes so that no actual space develops at the fracture site.

REASONS FOR NONUNION

It has been our impression that accurate reduction and proper nailing of the fragments influence union. This impression is substantiated by the fact that 72.5 per cent of the unions had good or excellent reductions and nailings; however, there was union in 27.5 per cent in which the reduction and nailing were fair or poor. In nonunion, 13 of the 27 were attributed to poor reduction, inadequate mechanical fixation or premature removal of the nail. The remaining 14 nonunions followed satisfactory reductions and nailings, but 2 were in patients with Paget's disease involving the head and the neck of the femur.

It has been felt that the greater shearing force exerted in the Pauwel type 3 fracture renders it more prone to nonunion. In this series, the percentage of nonunion for type 2 and 3 fractures is shown in table 4. There was no significant difference between the average age (less than one year) of type 2 and type 3 fractures. From these statistics, it will be seen that the percentage of nonunion in type 2 fractures is 16.5 per cent, while the percentage of nonunion in type 3 fractures is 10.5 per cent. It is true that the number of type 3 fractures is small, but still the difference is enough to be suggestive. With adequate internal fixation, the shearing force at the fracture line is probably eliminated. If the internal fixation accomplishes this, then one would expect type 3 fractures to unite in a higher percentage than type 2 fractures, as there is more osseous tissue in apposition. Without internal fixation, as in a Whitman cast, the shearing force cannot be entirely eliminated. Under these circumstances, nonunion would probably be higher in the type 3 fractures.

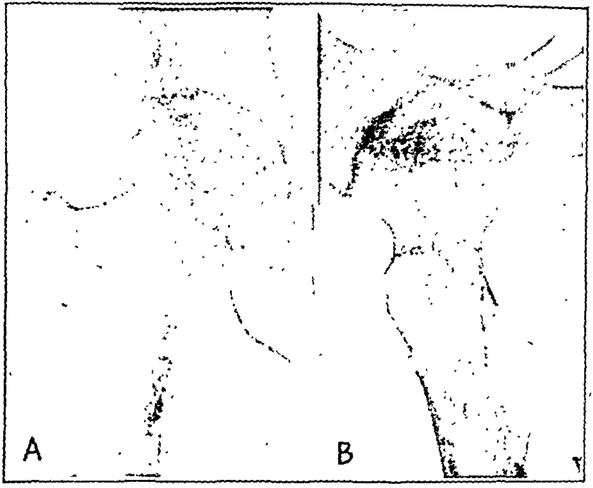

Fig. 4—Same hip as in figure 3 four years and four months following the operation, illustrating solid bony union without aseptic necrosis or arthritic changes.

Table 4.—*Comparison of Union and Nonunion in Pauwel's Type 2 and Type 3 Fractures*

	Hips	Union	Nonunion	Nonunion Percentage
Type 2	139	116	23	16.5
Type 3	38	34	4	10.5
Total	177	150	27	15.3

Aseptic necrosis of the head of the femur was present in 32.6 per cent of the patients that obtained union, 59.3 per cent of the hips with nonunion showed aseptic necrosis. These data indicate that aseptic necrosis is a factor in the production of nonunion, but that it does not preclude union.

ARTHRITIC CHANGES

The percentage of arthritic changes is shown in table 5. There were 105 hips followed from one to two years. Of these, 15.7 per cent showed moderate ar-

Table 5.—*Arthritic Changes in Hips With Bony Union*

	Hips	Arthritic, Moderate, Percentage	Changes, Severe, Percentage
Follow-up 1-2 yr.	105	15.7	5.7
Follow-up over 2 yr.	45	22.2	33.3
Total	150		

47 hips with arthritic changes, 31.3%.

thritic changes, while 5.7 per cent showed severe arthritic changes. In the 45 hips with union followed two years or longer, these percentages increased to 22.2 per cent for moderate arthritic changes and 33.3 per cent for severe arthritic changes. These data show that there is an increase in the severity of the arthritic changes with time and use. In this study, the arthritic changes in the head of the femur were classified as 1 plus, 2 plus, 3 plus and 4 plus (figs. 1 and 2). In table 5, 1 plus and 2 plus arthritic changes are classified as moderate and 3 plus and 4 plus arthritic changes as severe. Slight roughening of the head of the femur was considered 1 plus arthritis. A slight depression and irregularity of the head of the femur was considered 2 plus. Moderate but definite collapse of the head was classified as 3 plus, and pronounced collapse with irregularity of the head was classified 4 plus. From a clinical point of view, we have observed that patients with moderate arthritic changes have slight pain in the hip but are able to walk rather well, either without support or with the use of a cane. Patients with severe arthritic changes have considerable pain and often require the use of a cane or crutches. When 4 plus arthritic changes are present, there may be more or less constant pain even at rest. Such a patient may be more disabled than one with a nonunion. Orthopedic surgeons have devised many operations for the treatment of nonunion following fractures of the neck of the femur. The treatment of these patients is still a definite problem. However, the statistics presented in this paper indicate that in patients followed two years or longer there will be a larger number with severe arthritic changes than with nonunion. Accordingly, in the future it will be necessary for us to direct our attention toward the treatment of this unfortunate complication, as we have toward nonunion in the past.

CONCLUSIONS

The mortality in 360 fractures of the neck of the femur has been 7 per cent. The mortality varied from 0 in the sixth decade to 42.9 per cent in the tenth decade.

Bony union occurred in 84.7 per cent of the patients followed for one year or longer. In our experience, Pauwel's type 3 fractures have not shown a predisposition to nonunion as compared with type 2.

The incidence of aseptic necrosis is higher in patients with nonunion than in those with union, approximately 60 per cent in the former and 33 per cent in the latter.

Arthritic changes following bony union gradually increase in percentage and severity with time and use until the percentage of severe arthritic changes in patients followed two years or longer represents approximately one third of the cases. After the use of internal fixation, the percentage of patients in whom severe arthritic changes develop will exceed the number with nonunion. Consequently, the development of methods for the treatment of severe arthritic changes following union assumes even more importance than the treatment of nonunion.

While the data presented in this paper appear discouraging, this does not alter the fact that internal fixation is the treatment of choice for acute fractures of the neck of the femur. The mortality is lower, the patient is more comfortable; medical complications are less frequent, the percentage of senile psychosis is greatly reduced, the cost of hospitalization is diminished and the percentage of bony union is greater than with any other method.

TREATMENT OF UNUNITED FRACTURES OF THE NECK OF THE FEMUR

JAMES A. DICKSON, M. D.
Cleveland

As the other speakers in this symposium have pointed out, modern conceptions of treatment of fractures of the neck of the femur are focusing on the importance of elimination of shearing force on the fractured surfaces and of maintenance of circulation to the head in producing satisfactory results. The use of internal fixation has increased the number of cases in which union is obtained from about 50 to 80 per cent, but there is growing recognition that this method has not entirely solved the problems presented by intracapsular fractures, and increasing attention is now being paid to functional results. Nonunion results after simple nailing in about 18 to 20 per cent of cases, and atrophy of the head and arthritic changes also occur in another large group in which the fracture unites, so that treatment is actually unsuccessful from the functional point of view in about 35 to 50 per cent of intracapsular fractures of the femur.[1]

Those cases in which nonunion is associated with pronounced aseptic necrosis and absorption of the head and secondary arthritis changes, for which the treatment to be considered lies between a reconstruction operation or an arthrodesis of the hip, will not be dealt with at this time. This discussion of treatment of ununited fractures of the femoral neck will be confined to those cases in which it would seem possible and feasible to restore anatomic and physiologic function to the hip joint. Fortunately, the greater proportion of patients with ununited fracture of the femoral neck are reasonably suitable candidates for further surgical care. When it is recognized that nonunion is developing this fact should be accepted immediately and an appropriate operation for correction carried out. When nonunion once starts, it almost invariably goes from bad to worse, and the longer operation is delayed, thus allowing atrophic changes to develop in the head, the more problematic the end results of secondary treatment. The earlier the oper-

ation is performed after nonunion has been established, the better the results that can be expected. With a better understanding of the basic principles involved in the causation, with consequent earlier recognition and treatment of beginning nonunion, it is hoped that many of the more extensive reconstruction procedures can be avoided, or at least that the need for them can be greatly minimized.

The factors of mechanics and circulation—which are closely interrelated—are of utmost significance in planning treatment of fractures of the neck of the femur which have failed to unite. In these instances, as has been demonstrated by the investigations of Pauwels,[2] Linton[1b] (fig. 1) and Eyre-Brook and Pridie,[1c] the mechanical factors are unfavorable, in that the angle of the fracture tends toward the vertical—when measured in relation to the femoral shaft—the fracture is not impacting, and shearing force tends to produce instability and pull the fractured surfaces apart. In a large proportion of these cases, also, roentgenograms show increased density of the head as compared with the femoral shaft, a finding indicating that blood supply to the amputated head is inadequate or lacking and that this portion of the bone is undergoing *aseptic necrosis*. Whether or not this bony change occurs in the head depends on the degree of interruption of the blood supply, which is determined by the position of the fracture within the capsule as well as the angle of the fracture. When circulation is preserved in both fragments, and the fracture is in an impacting position, then union results, and aseptic necrosis of the head rarely occurs. When circulation of the head fragment is greatly impaired, then union is delayed, and if the process is too slow, *aseptic necrosis of the head* may develop. In some cases in which shearing strain may prevent union, the amputated fragment of the head may remain viable because of blood supply received through the capsular vessels and perhaps the ligamentum teres.[3] However, it is well established that the principal blood supply to the head of the femur is by way of the medullary vessels which pass through the neck. In the treatment of ununited fractures, then, the earlier this main source of blood supply can be restored through the neck by impaction of the fracture and stimulation of osteogenesis and revascularization, the better the results should be.

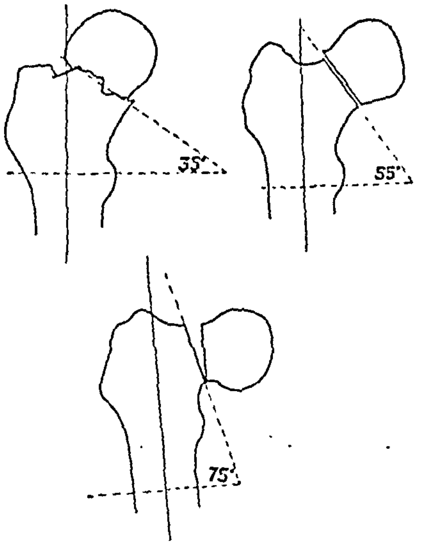

Fig 1.—Mechanical analysis of fractures at the neck of the femur, according to Linton.[1b]

BONE GRAFTING AND OSTEOTOMY

In the treatment of ununited fractures in other parts of the skeletal system, it has long been recognized that satisfactory results depend on correction of faulty mechanics and stimulation of osteosynthesis by bone grafting. In the treatment of ununited fractures of the neck of the femur, however, reliance has been placed in the past on bone grafting procedures which did not take into account the mechanical factor largely responsible for the nonunion or on osteotomy procedures attempting to place the fracture in an impacting position, which did nothing to replace the fibrous tissue that had formed at the fracture site or to facilitate osteogenesis and revascularization of the head. Hence bone grafting and osteotomy are both only partial remedial procedures, in that each fails to take into account the whole problem presented by ununited fractures of the neck of the femur. Nevertheless, both methods have produced satisfactory results in a certain proportion of cases. Hence there has been a tendency for the individual surgeon, on the basis of his experience, to develop a preference for one or the other. This empiric attitude has undoubtedly been responsible for many failures by both methods since it has failed to recognize the fact that a certain proportion of cases in which bone grafts are used will result in failure when shearing force on the fracture line remains great and—conversely—that an osteotomy will not be successful when the desired impaction is not obtained because of lack of accurate control of the rotation of the head or when the degenerative fibrous process at the fracture site has progressed so that circulation cannot be reestablished through the neck to stimulate osseous repair.

The principal technics used for bone grafting in ununited fractures of the femoral neck are those described by Albee, Henderson[5] Gallie,[6] Compere[7] and myself.[8] Bone grafting technics are much alike in principle; the differences consist largely in the source of the bone used; i. e., tibia, fibula or ilium; whether the grafts are single or multiple; the site of insertion of the graft; the type of incision and exposure used in performing the the operation, and whether or not the graft is accompanied by some method of internal fixation.

The aim of all bone grafting procedures is to replace fibrous growth by formation of new bone, stimulated by transplantation of healthy bone into the area of degenerative change. If shearing force is not too great, and if the graft is well placed so as to aid in overcoming instability of the fracture, satisfactory results may depend partially on this mechanical factor. However, even in cases in which osteogenesis is stimulated satisfactorily, the results of the operation may be unsuccessful because the mechanical fault has not been corrected and the new bone is subjected to the same stresses that caused or contributed to the nonunion of the fracture originally.

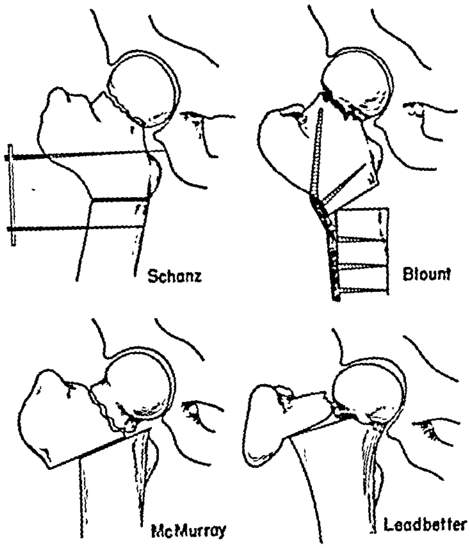

Fig 2.—Various types of osteotomy procedures for ununited fractures of the neck of the femur.

Nearly all who have used bone grafting procedures have recognized that such operations were not suitable in all cases. In general, the tendency has been to confine the use of bone grafting to patients in younger age groups. Usually bone grafting is regarded as a suitable procedure in only about 10 per cent of patients with ununited fractures of the femoral neck.[9] Published results show that operations of this type result in union in only about two thirds of this selected group of cases.[10]

The purpose of various types of osteotomy (fig. 2) is to correct the mechanical fault that is preventing impaction and to produce a stable hip.[11] In the Schanz,[11c] or wedge, osteotomy, shearing force is often overcome, giving greater stability to the hip joint, but it often does not result in union, and causes considerable loss of leg length.[12] The McMurray,[11f] or high oblique, osteotomy is now considered preferable to the Schanz procedure by most orthopedic surgeons. With this operation, union of the osteotomy surfaces occurs, thus yielding a stable hip even in cases in which nonunion between the head and neck of the femur persists. The shortening of the leg following this operation, although it may be considerable, is not so great as with the wedge osteotomy. The principal difficulty with the McMurray osteotomy is lack of definite control of the head of the femur and upper trochanteric segment and their proper placement when the shaft of the femur is displaced medially. In many instances, the head of the femur is not rotated sufficiently and the fragments are not correctly placed to facilitate bony union and repair. Impaction of the fragments is relied on entirely to break down the fibrous scar tissue, and when much scar tissue is present, or when sufficient impaction is not procured, union cannot occur. Unfavorable results with osteotomy alone, in the presence of a "dead" head, were undoubtedly due to the fact that union was not procured between the shaft and the head and consequently there was never any possibility that the head might become revascularized.

[12] Linton.[1b] Schumm.[11d] Reich.[11e]

The Leadbetter[11m] cervical-axial osteotomy overcomes some of the difficulties of the McMurray procedure in that the osteotomy is done under direct vision and greater leg length is procured than with the other types. However, there is still lack of control of the degree of rotation of the fragments, and, except in early cases, in which operation is performed before much fibrous tissue has developed at the fracture site, the procedure is carried out with considerable difficulty.

Although the Brackett operation[13] is a reconstruction procedure, it rests on essentially the same principles as osteotomy, since its aim is to correct the mechanical fault and to remove the shearing stress from the fracture site. It has the additional advantage that it removes fibrous tissue at the fracture and thus attempts to "freshen" the bone for healing. Although this procedure is preferred to osteotomy by some surgeons,[14] and although in my hands it has produced some satisfactory results, I agree with Watson-Jones[15] that it is not to be recommended because the extensive dissection required produces much greater interference with circulation than does osteotomy, and thus may inflict further injury on an already damaged blood supply.

Thus a critical analysis of my own results with various procedures used in treatment of ununited fractures of the neck of the femur and a review of the literature reporting the different bone grafting, osteotomy and reconstruction procedures show that, although results are satisfactory in some instances, the proportion of failures is remarkably similar with all methods, amounting rather generally to 35 to 50 per cent of all cases subjected to secondary procedures.

This led to the idea that if the advantages of the various procedures could be combined, with aim of correcting faulty mechanics and restoring circulation and stimulating formation of bone in a single operation, perhaps these results might be improved. Examination of a series of roentgenograms of ununited fracture of the femoral neck showed that in most instances there was a downward rotation of the head of about 60 degrees. Furthermore, measurement of the angle of the fracture line in relation to the femoral shaft, by Linton's method, showed that in all instances this was high, i. e., over 65 degrees, and hence would fall in the group classification of Pauwels[2] and Linton[1b]; this is the group in which shearing force is greatest and mechanical factors are most unfavorable to union.

In planning the treatment of ununited fractures, it thus seemed evident that if the upper part of the shaft and head were rotated 60 degrees, the head of the femur would assume its normal relationship within the acetabulum, and the mechanical stress in the fracture line would be changed so that the fracture would have the advantage of impaction to stimulate union. That is, according to Linton's classification, it would be changed from group 3 to group 1, for the angle of inclination of the fracture would be changed from 65 degrees or over to less than 30 degrees. Thus, according to modern concepts, a controlled osteotomy is essential in the treatment of nonunion of fracture of the femoral neck.

In view of the fact that elsewhere in the skeletal system results of treatment of ununited fractures depend not only on the correction of mechanical faults but also on bone grafting to stimulate osteogenesis, it is logical and desirable that this 60 degree rotation of the head and trochanteric segment should be combined with bone grafting to stimulate osteogenesis. A bone graft gives added stability across the fracture and acts as a guide to formation of granulation tissue and aids revascularization of the head. This facilitates blood supply from the trochanteric segment to the head and leads to more rapid healing. Hence it is obvious that bone grafting is also essential in the treatment of ununited fractures at the neck of the femur. The use of cancellous bone for the graft taken from the ilium is important, as has been shown by the work of Abbott and his collaborators.[16] "Cancellous bone has a loose structure, with interlacing and branching trabeculae, every one of which is covered by endosteal cells, and has high osteogenetic power. The loose structure also permits of early and thorough revascularization."

This reasoning led to the development of the combined procedure,[17] consisting of the high geometric osteotomy in which the rotation of the head and trochanteric segment is accurately and consistently controlled and brought into a position of maximal impaction, with insertion of a bone graft from the ilium to stimulate osteogenesis and revascularization.

TECHNIC

The method employed to procure an osteotomy that will assure a 60 degree rotation and bring the fractured surfaces into a position of impaction is illustrated in figures 3 and 4. The operation is

17a. Since this paper was presented the technic has been modified: a single curved lateral incision between the tensor fascia femoralis and the gluteus medius muscles or an anterior femoral incision is used.

carried out through two incisions.[17a] A lateral incision, 7 to 8 inches (17.8 to 20.3 cm.) long, extends downward from the prominence of the greater trochanter. The outer surface of the bone is exposed subperiosteally, and a bed prepared for insertion of a blade plate. Then a Smith-Petersen incision is made to expose the hip joint from the front. The rectus femoris is reflected downward, allowing full exposure of the anterior surface of the femur. The joint capsule is opened and the incision carried outward with medial reflection of the muscles anterior to the femur.

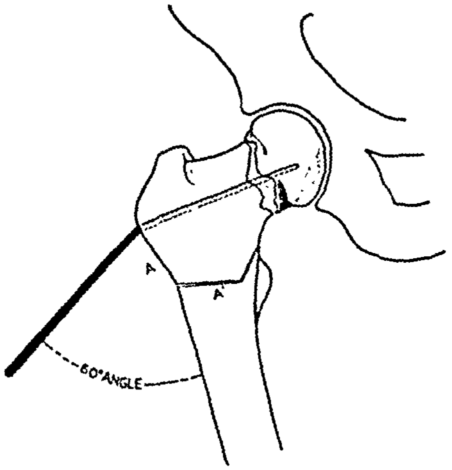

Fig 3.—Site for geometric osteotomy and control of upper segments by blade plate.

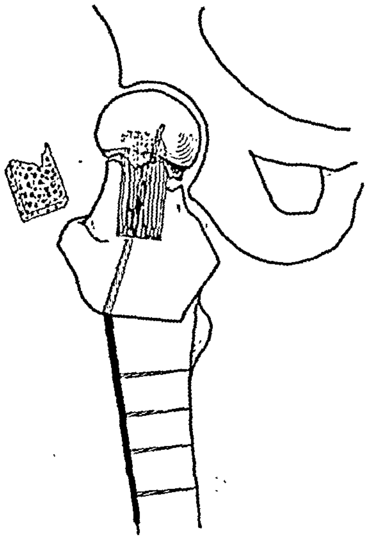

Fig 4.—Position of osteotomy after rotation and placement of bone graft.

To assure control of the head and trochanteric segments, these are transfixed by a blade plate, extending from the prominence of the greater trochanter well into the lower half of the head. A guide wire is first placed from a point about ½ inch (1.3 cm.) above the prominence of the greater trochanter into the center of the head. Then the blade plate is suitably bent so that when the blade is inserted parallel to the guide wire, the plate will extend outward from the shaft at a 60 degree angle. This is readily accomplished with the aid of a protractor. With the blade plate properly placed, the osteotomy site is then determined. In order to procure the desired rotation, the osteotomy should be cut to simulate the sides of a regular hexagon (fig. 3). Then when rotation is carried out (fig. 4) and the side A comes to A^1, the segments will fit accurately, the desired rotation of 60 degrees will be accomplished and the plate will fit along the shaft of the femur.

The osteotomy site is determined by measuring with a caliper (fig. 5) the distance from where the blade enters to the lesser trochanter. This gives the diameter of the marking chisel which is chosen from a set of six semihexagonal chisels. When the proper-sized marking chisel is used and placed on the front of the femur with the diameter extending from the entrance of the blade plate to the lesser trochanter, one side of the marker extends beyond the flare of the trochanter. If the chisel is now rotated slightly so that one side runs parallel to the flare of the trochanter, extending downward from the entrance of the blade plate, the site of the osteotomy can be marked. This brings the inner blade out just above the lesser trochanter, thus assuring a high osteotomy. If too small a marker is chosen, the osteotomy will extend into the neck, and much of the support of the head segment will be lost. If too large a chisel is used, then the osteotomy will come out below the lesser trochanter, and the impacting force of the psoas will not be procured. The measurement determining the choice of the proper marking chisel is extremely important, in order to obtain optimal results from the osteotomy.

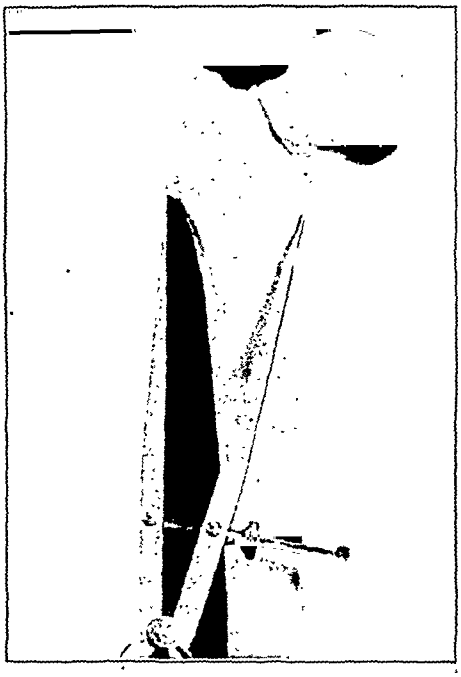

Fig 5.—Estimation of size of marking chisel to be used for osteotomy, from the point of insertion of the blade plate to the lesser trochanter.

When the osteotomy and rotation have been completed, a window is made in front of the trochanteric segment just distal to the fracture site (fig. 4). This readily allows removal of sclerotic bone and fibrous tissue and curettement up into the head to facilitate placement of the graft. Numerous chips of cancellous bone from the ilium are impacted well across the fracture line, and one large graft is then fixed into position to give added stability. The window removed can be replaced.[8] As has already been mentioned, cancellous bone is used because it has superior osteogenetic power.

Internal rotation is maintained in balanced traction, or with a plaster boot and bar, for six to eight weeks; then the patient is allowed up on crutches, with no weight bearing for a period of months. Roentgenograms are made as progress studies from time to time, and protection is continued until there is evidence that the head is throughly revascularized.

COMMENT

Fortunately, this rotation osteotomy results in equalization of leg length, and the greater the varus deformity before operation, the greater the length procured (fig. 6). Full details of the effect of the geometric osteotomy on leg length have been reported previously.[17] This approach to the treatment of ununited fractures of the neck of the femur has produced most encouraging results. In the 10 cases in which operation has been performed, solid bony union has been procured in 9. The one case in which union has not occurred has resulted in a good, stable, functioning hip. This was one of the early cases in the series, and it is believed that insufficient attention was given to the placement of the graft in this instance. Figure 7 illustrates the results obtained.

The cases dealt with in this series have not been "favorable" cases, in that the nonunion has been of long standing in most of them, and, in several, roentgenograms have indicated increased density in the head fragment, indicating considerable degree of aseptic necrosis. In these instances, there is roentgenographic evidence that healthy bone has formed in the head, which indicates that there has been reestablishment of circulation to the head through the medullary vessels of the neck as a result of the combined operation.

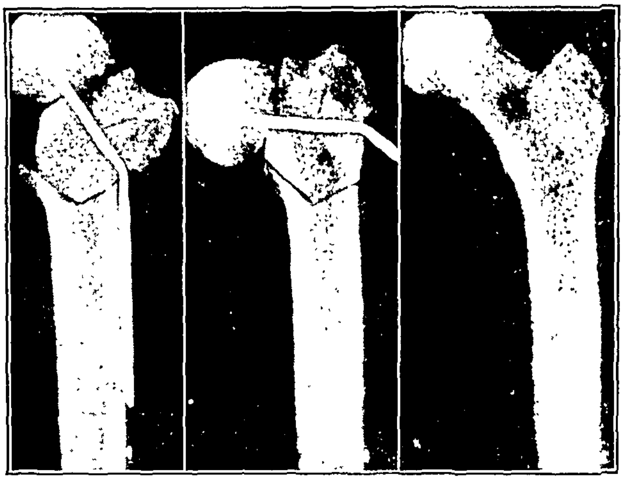

Fig 6.—Equalization of leg length by geometric osteotomy.

As these cases indicate, and as others have also shown after bone grafting[7] and after osteotomy procedures,[18] a so-called dead head can be revascularized and returned to a normal state both roentgenlogically and functionally. These findings naturally suggest that perhaps orthopedic surgeons should question carefully the present concepts regarding necrotic heads after femoral neck fractures. This is a controversial problem because, according to some orthopedic surgeons, the roentgenographic findings and the duration of nonunion in the cases shown would have been interpreted as criteria indicating the need for a reconstruction operation of the Whitman or Colonna type, with removal of the head. These operations are unquestionably necessary in some instances, and there is no intent to imply that all cases of ununited fractures of the femoral neck should be treated by the combined procedure here described. However, there is now considerable difference of opinion as to what

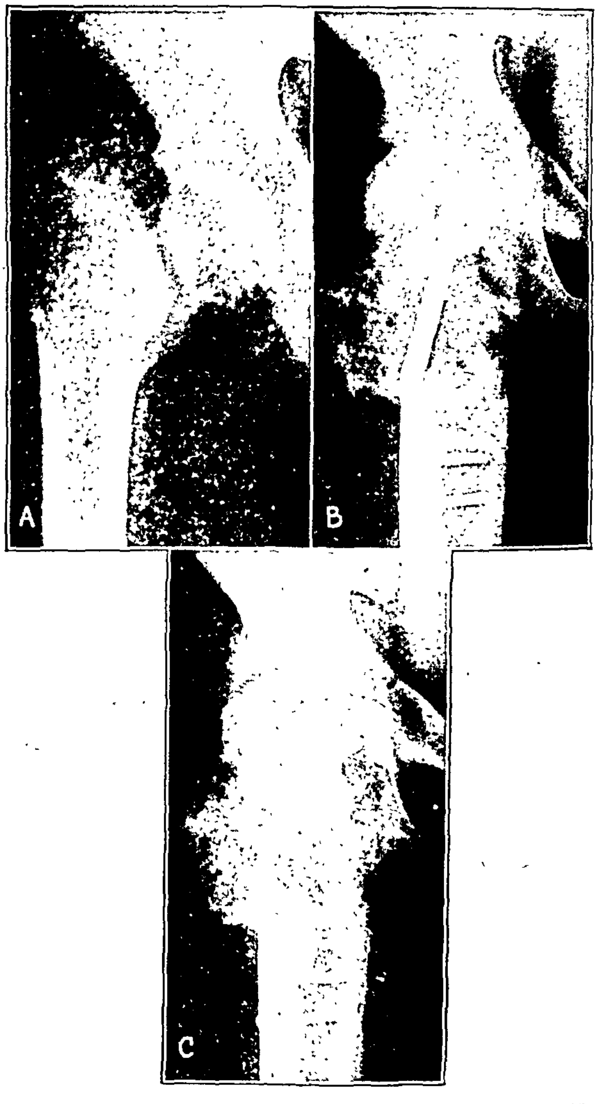

Fig 7.—(A) Preoperative anteroposterior roentgenogram of ununited fracture of femoral neck in a man, 42, twenty-one months after injury. Note roentgenographic evidence as the "dead" head. (B) postoperative anteroposterior roentgenogram of same patient, showing union and evidence of revascularization of head, six months after operation. (C) anteroposterior roentgenogram of same patient, showing solid bony union and regeneration of healthy bone in the head, eleven months after operation.

18. (a) Linton.[1b] (b) Phemister, D. B.: The Pathology of Ununited Fractures of the Neck of the Femur with Special Reference to the Head, J. Bone & Joint Surg. 21: 681-693, 1939. (c) Sherman, M. S., and Phemister, D. B.: The Pathology of Ununited Fractures of the Neck of the Femur, ibid. 29:19-40, 1947.

constitutes a "dead" head and as to the procedures that may be effective in the presence of roentgenographic evidence of aseptic necrosis. Wolcott[3a] reported that pathologic examination of three femoral heads, removed in performing Whitman reconstruction procedures, which had shown definitely increased roentgenologic density in relation to the femoral shaft, proved that in none of them was there complete necrosis of bone.

At this point, it seems desirable to question the practice of sacrificing all so-called dead heads, as is recommended by some. It must be admitted that at present our knowledge is not sufficiently definite to permit the formulation of any dogmatic dictums regarding these cases. Nevertheless, if surgeons free themselves from rigid, perhaps erroneously pessimistic conceptions as to the potential viability of femoral heads which have been amputated by ununited fractures, it may be that many such heads, which are now sacrificed because of such conceptions, may be saved. It would seem wise to assume a cautious and conservative attitude toward removal of "dead" heads, since, according to the facts cited, there is possibility for regeneration of bone in a large proportion of these cases.

If this conservative attitude is assumed, one must not lose sight of the fact that although there may be some question as to the degree of vascular damage there is no question that the nutrition of heads which show increased density on the roentgenogram has been impaired. This means, as Phemister[18bc] has emphasized, that such a head must be protected from trauma incident to weight bearing for a prolonged period—at present just how long is not known—while the new bone is forming. For it seems inevitable that if the head is not protected during this period of regeneration, atrophic and arthritic changes will occur.

If time proves that despite the evidences of regeneration in these heads there is eventual atrophy in some of them, then, with the type of osteotomy here used, arthroplasty[19] with the "vitallium" cup, as described by Badgley, can still be employed. This would not be possible after other types of osteotomy. If this is not feasible in a particular case, then a Whitman[20] or Colonna[21] reconstruction operation, or an arthrodesis, as recommended by Gill[22] for cases in which the head is collapsed, could be performed.

Since the combined operation has resulted in evidence of regeneration and revascularization of bone in roentgenologically "dead" heads in cases of two and three years' duration, it seems logical to assume that the treatment might be expedited and the results more certainly favorable in earlier cases of nonunion. From what is now known of the effect of unfavorable shearing stress and of circulatory impairment in the causation of nonunion and of atrophic changes in the head, it is to be expected that a rationale may be developed, aiming toward the prevention of many of these complications of fractures at the femoral neck.

The mechanical analysis of the fracture angle in relation to impaction and the position of the fracture in relation to the interruption of blood supply furnish an approach toward classification and prognosis of cases at the time the fracture occurs. In cases in which preliminary study indicates that impaction is unlikely to occur with simple nailing, then some type of operation designed to bring about impaction and stability of the fracture should be performed as a primary procedure. Bone grafting has been recommended[23] for this purpose, and also osteotomy.[24] It may be that bone grafting will be effective through stimulation of osteogenesis and in adding sufficient stability in some such fractures to prevent nonunion. From the standpoint of basic principles, however, it would appear that a controlled osteotomy would be preferable to any type of bone grafting in overcoming the mechanical factors most unfavorable to union[25].

It might be, with proper selection of cases and of the primary procedure best suited to the individual case, that development of nonunion and also of atrophic changes might be largely avoided. If so, this would be a big step forward in the treatment of ununited fractures of the neck of the femur, since an ounce of prevention is worth a pound of cure. When nonunion is evident, it is important that combined osteotomy and bone-grafting operation be performed as early as possible. Slipping of the fractured surfaces is usually discerned on the roentgenogram within the first few weeks, and in the vast majority of cases in which this occurs the situation progresses steadily and there is eventual nonunion. If union does occur in such cases, it is long delayed and is usually accompanied by severe atrophic changes. In these cases, instead of waiting and hoping blindly for a favorable outcome, which almost

never happens, the secondary operation should be performed immediately, assuming that the patient's general condition warrants it. This would establish impaction and revascularization and regeneration of bone before all the troublesome fibrosis and atrophic changes have occurred to complicate the situation.

If surgeons reorient their conceptions of the problem of nonunion of fractures of the neck of the femur in this direction—that is, toward early recognition of unfavorable mechanical and circulatory factors, and institute prompt treatment by means of the combined operation, it seems probable that the results in this type of case would be greatly improved.

ABSTRACT OF DISCUSSION

On Papers by Drs. Van Gorder; Cleveland, Bosworth and Thompson; Freyberg and Levy; *Badgley and Denham*; Boyd and George; and Dickson.

DR. J. R. MOORE, Philadelphia: Dr. Van Gorder has covered the fundamentals essential to the successful treatment of this type of fracture. It is important to recognize in these patients the important part that pain plays prior to reduction, which one might term as a complete change in personality. The patient becomes morose, depressed, psychotic. These findings, coupled with the general changes concommitant with age, suggest poor mental and physical health and delay surgical treatment. A vicious circle develops. The patient becomes totally invalided, suffers from complete enforced immobilization and the pain factor. A complete physical examination is essential and a roentgenogram of the chest is advisable as a matter of routine. The observations rarely delay a reduction legitimately. Adequate therapy, of course, should be employed to meet the coexisting conditions, complications in connection with surgical treatment. After the fixation of the fracture, a dramatic change in personality and general physical being occurs which bears out beyond question the significance of the pain element. The second point which I wish to emphasize deals with the method of reduction. Gentleness is essential. Violent maneuvers are unwarranted and only serve to rotate the head, perhaps even rupture the capsule or tear the blood supply attachment to the head fragment. The simple method of pulling both extremities gently to length, holding the pelvis firmly in the normal transverse axis, then gently internally rotating the fractured extremity until the internal rotation matches up with the internal rotation present on the opposite side and finally mildly abducting for a few degrees for locking brings about an anatomic reduction in the majority of instances. In case reduction is not accomplished, then one should resort to open reduction at once, refusing anything short of normal restoration. I wish to emphasize the importance of follow-up. The usual anteroposterior and lateral views should be taken, and roentgenograms should be made at monthly intervals for the first six months, at intervals of two months for the second six months, every three months for the third six months and then at intervals of six months for a minimum period of three years. It is only in this manner that early nonunion can be anticipated or diagnosed and that aseptic necrosis and avascular necrosis can be discovered and adequate treatment instituted.

DR. ROBERT H. KENNEDY, New York: The paper by Drs. Cleveland, Bosworth and Thompson is an important presentation. Comparison is made between a large group of patients treated by internal fixation and one treated by closed methods. Our experience at the Beekman-Downtown Hospital has not been exactly similar. In our group of 34 patients in the past six years, the average age was 63, as compared with 75 in Dr. Bosworth's report. Whatever variance we might find in complications and results might readily be due to a difference of twelve years. Only 20 per cent of our group were over 70, quite at variance with the group just reported. Our major treatment has been by Russell traction, and only 5 of this group had internal fixation. The mortality among patients treated in traction was 7 per cent, differing greatly from their mortality of 36 per cent when treated by traction, or 12 per cent by internal fixation. There was no mortality in our 5 patients treated by internal fixation. It seems that it makes a great difference what type of person one handles. The duration of traction in our cases averaged sixty-seven days. We no longer depend on adhesive plaster on the leg but use a Kirschner wire through the os calcis. As regards decubitus, which Dr. Bosworth and his group stated was almost the rule with traction treatment, this occurred in only 10 per cent of our patients. The frequency of stiff knees was low. We expect a good functional result following the use of Russell traction for as long a period as nine to ten weeks. There were 3 patients, 10 per cent, who experienced serious complications. One had a pulmonary infarct, and 2 had pneumonia. The hospital stay for traction cases was ninety-three days, compared with ninety-eight, and for internal fixation fifty-four, compared with fifty-seven. It is important to gain experience in internal fixation and have ready the proper setup for whatever nail one uses so that every hospital may do internal fixation when indicated. On account of low mortality, low morbidity, and lack of complications, we are in favor of continuing Russell traction in the majority of instances. In going over the paper, I did not note that it stated how soon these patients in internal fixation were allowed to be ambulatory. One must remember that in many instances, when one speaks of operating so that the persons may become ambulatory, one finds, on looking up the records, that one did not get them up early. Every one of these fractures can be expected to heal. There is little reason to go on record in favor of operating to avoid complications unless the patients are actually gotten out of bed.

DR. ALEXANDER P. AITKEN, Boston: I agree with Dr. Badgley that the terms "aseptic" and "avascular" necrosis are loosely applied. The correct term for death of the head following fracture or dislocation should be avascular necrosis. Inasmuch as death of the head cannot be determined for several months following fracture, all such fractures should be considered with suspicion. The high incidence of avascular necrosis is an argument for abstinence from weight bearing until one is reasonably sure that this condition is not going to develop. Even when there is avoidance of weight bearing, however, if the initial damage has been sufficiently severe aseptic necrosis will eventually develop. Phemister has proved that the underlying cause is rupture or thrombosis of the capsular vessels. One must therefore be most careful to prevent further damage. Consequently, all manipulation must be carefully done. I do not believe, however, that careful manipulation of a hip will do much to jeopardize the circulation of the head. I do not believe that any more harm is done by manual reduction than by the manipulation necessary in the application of skeletal traction. Dr. Badgley stated that union occurred in 90 per cent of his cases if traction was applied immediately. I do not recall, however, that he stated the incidence of avascular necrosis that occurred in this series. More careful study must be done before it is known whether or not the method of reduction plays a part in the development of aseptic necrosis. I would agree with Dr. Badgley that open reduction should be avoided whenever possible. Damage to the capsular vessels by surgical treatment must occur. However, many men are routinely operating on fresh hips, and it would be interesting to compare an incidence of aseptic necrosis in fractures treated by the open method with those treated by the pinning method. If, in two or three months or, as is more common, in six to eight months, it becomes obvious that aseptic necrosis has developed, Dr. Badgley has recommended weight bearing and protection until regeneration has occurred. If one could be sure that such regeneration would occur, such a procedure would be most advisable. The restoration of circulation with resorption of the dead bone and replacement of the head is a slow process. The chances of obtaining a normally shaped head with normal cartilage and without arthritic changes are rather small. Rather than submit our patients to such prolonged immobilization, in the presence of aseptic necrosis, my associates and I believe it wise to remove the head and perform a fusion of the hip or some type of reconstruction, despite the fact that the end results of these procedures leave much to be desired.

DR. WARREN WHITE, Greenville, S. C.: We have a rather definite responsibility in this section as regards the treatment of fractures. If you will go through some of the old programs of the American Medical Association you will notice the disappearance of papers on fractures in the Section on General and Abdominal Surgery. The responsibility, therefore, rests largely on this section, which, as I see, is being attended by so many general surgeons that we must get down to fundamentals and not be too technical in our discussions. I have a problem in South Carolina which is a considerable one. In the state there are only eight orthopedic surgeons. All eight of us cannot nail all the hips, and the general surgeons are still rather reluctant about doing hip nailing as a routine. At the risk of interjecting something which may be irrelevant to our subject this morning, I am going to ask whether one of our panel here will not discuss the more conservative method, surgically speaking, of taking care of these fractures of the neck of the femur if the surgeon is in a place where satisfactory hospital facilities are not available for hip fixation. What is the next best thing? I get many telephone calls from persons throughout the country trying to get into the hospital for fractures of the neck of the femur. We just do not have the hospital beds. I want to give these surgeons something to do that is better than Buck's extension.

DR. JOSE VALLS, Buenos Aires, Argentina: I agree, in a general way, with what the speakers said. I have used nailing in about 200 cases myself. I use traction for the first few days after admission of the patient, and I do the nailing during the first week, if it is possible. I used to handle the patients not with manipulation, but with slight traction and some internal rotation, and I succeeded in getting good reduction practically in all cases. I try to reduce the fracture not exactly, but to put the head in valgus position. That seems to me -- and I have been doing this during the last few years -- to help greatly in the union. After the nailing, I put a short plaster cast on for three months. If I need to move the patient, I use a special device to prevent weight bearing. I take off the cast after three months, and the patient walks with crutches, or some kind of braces, at least for six to nine months. I have been using a guide of my own in nailing for thirteen years. I think it is the best, but I believe that the proper position can be maintained with wires, with a screw, with bone graft or with a nail. The most important complication nowadays is aseptic necrosis. This is the field in which surgeons can do something in the next few years. In this field, Dr. Bado of Montevideo, Uruguay, claims that the bone graft, instead of nails, or screws, is better, and in his cases he has not seen so many with aseptic necrosis. In the intertrochanteric fractures, I have for many years used wire traction with the patient in bed, but now I have changed. I use a Neufeld nail, and I have about 20 cases in which this treatment was used. I am satisfied with the results because the patient can leave the bed in one week or more and go home in fifteen to twenty days. That cuts down the cost of the treatment.

DR. GEORGE W. VAN GORDER, Boston: To answer Dr. White, one realizes that there are a number of patients who are not close enough to hospitals to have the care that is necessary in hip nailing. The next best method of treating fractures of the neck of the femur, if one cannot nail them, is to use the Whitman abduction plaster of paris method. My third choice would be Russell traction. Figures on mortality mean little or nothing, unless the length of time that is involved and the complete data regarding them are known. Do I believe in leaving alone impacted types of fractures in group 1? For many years, we never nailed an impacted fracture, but we allowed it to go on to union, expecting it to unite and finding that it nearly always did unite. Later we became too certain of our judgment and on a rare occasion were deceived by the roentgenograms, only to find that the apparent impaction was not real and did not hold. In view of the uncertainties of roentgen interpretation in these cases, some of my colleagues and I now prefer to nail impacted fractures of the femoral neck as well as the unimpacted ones. I would treat the extremely high subcapital fracture in an elderly woman by internal fixation with a Smith-Peterson nail and possibly would use a bone graft as well, depending on the obliquity of the fracture line. I am asked why, in an oblique or vertical fracture of the femoral neck, the third type which is so hard to unite, I do not do an osteotomy as a method of choice. There, again, it is a matter of personal opinion. It was with extreme interest that I heard Dr. Boyd speak this morning about his results with Pauwels' group 3 type of fracture. Apparently in Boyd's experience, these patients did as well under similar treatment as those of a supposedly more favorable type.

DR. HAROLD B. BOYD, Memphis, Tenn.: If we are to learn more about aseptic necrosis, adequate follow-up roentgen studies must be made on a large number of patients. In addition to the usual postoperative roentgenograms, we endeavor to secure anteroposterior and lateral roentgenograms of the hip two and six weeks after the operation; then roentgenograms are taken every three months for a year and each six months the second year. If possible, roentgenograms should then be taken of the hip at least once a year as long as the patient lives. In regard to thirty hours. This has afforded the opportunity to compare results in the first instance with those in a group receiving the same type of penicillin alone in seven and one-half days. We have not treated early syphilis with penicillin alone in thirty hours, but the results of the second schedule may be compared to the first and to those obtained with the same amount of penicillin given by the interrupted intramuscular method over three and three-quarter days.[5]

SCHEDULE A

One hundred and twenty patients exhibiting dark field positive lesions of primary or secondary syphilis were prepared for treatment.[6] One hundred and nine patients were completely treated by the following schedule within the period from Jan. 4, through July 29, 1945. Each patient received 20,000 units of sodium penicillin intramuscularly every three hours for sixty doses, over seven and one-half days (1,200,000 units total) plus three 3 hour sessions of artificial fever at 106 F. (rectal) level on alternate days, beginning twenty-three hours after penicillin was started. No further treatment was given unless clinical or serologic failure or pregnancy occurred.

Observation of these patients over a maximum period of twenty-three months and a minimum of sixteen months is presented.

The distribution of patients according to age, sex and race is given in table 1. The age of the patients ranged from 15 to 40 years; 21.1 per cent were under 20; 43.1 per cent were 20 to 24 years of age; and 35.8 per cent were 25 or over. There were 9 (8.3 per cent) cases of primary seronegative syphilis; 27 (24.7 per cent) of primary seropositive syphilis (including 2 reinfections); 64 (58.7 per cent) of secondary syphilis (including 1 reinfection), and 9 (8.3 per cent) cases of relapsing early syphilis.

TABLE 1.—*Patients Treated According to Schedule A: Number and Percentage of Patients Grouped by Race, Sex and Age*

Race and Sex	Age in Years							
	Number				Percentage			
	Total	Under 20	20 to 24	Over 24	Total	Under 20	20 to 24	Over 24
Total... ...	109	23	47	39	100.0	100.0	100.0	100.0
Male......	46	11	13	22	42.2	47.8	27.7	56.4
Female...	63	12	34	17	57.8	52.2	72.3	43.6
White......	19	1	11	7	17.4	4.3	23.4	17.9
Male......	8	..	4	4	7.3	...	8.5	10.3
Female...	11	1	7	3	10.1	4.3	14.9	7.6
Negro......	90	22	36	32	82.6	95.7	76.6	82.1
Male......	38	11	9	18	34.9	47.8	19.2	46.2
Female...	52	11	27	14	47.7	47.8	57.4	35.9

The results of treatment at designated intervals are summarized in table 2 for the whole group, and demonstrated in chart 1 by stage of disease.

The percentages used for the chart on successes and failures were obtained by assuming that patients lost from observation would have shown the same ratio of results of treatment as those observed. The ratio of the number of patients observed in each period to the number observed in the preceding period was applied to the cumulative failure figure. Patients with positive significant serologic titers[7] after twelve months' observation have been grouped with failures. Those who were seronegative or who maintained nonsignificant titers were, for the present, considered successes.

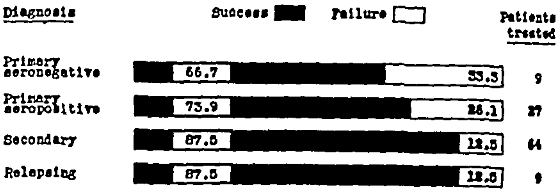

Chart 1.—Percentage of successes and failures by diagnosis at end of first year's observation of 109 patients treated according to schedule A.

TABLE 2.—*Patients Treated According to Schedule A: Results and Number of Days from Beginning of Therapy*

Number of Days from Beginning Date of Therapy	Number of Patients			
	Total Observed During Period or Later	Serologic Titer		Failures
		Negative	Positive	
0- 29	109	12	97	..
30- 59	99	23	76	..
60- 89	94	30	64	..
90-119	92	39	46	7
120-149	85	45	37	3
150-179	81	52	26	3
180-209	73	51	21	1
210-239	68	51	16	1
240-269	63	49	14	..
270-299	63	53	9	1
300-329	58	51	7	..
330-359	53	51	2	..
360-419	50	50	..	..

All lesions healed immediately after treatment. There was, in general, no pronounced difference in the rate of healing from that observed with similar amounts of penicillin alone.

Sixty-eight of the 100 seropositive patients achieved seronegativity after treatment. Four (5.9 per cent) of these subsequently relapsed. One patient was retreated because of pregnancy.

A lumbar puncture was performed on all but 2 of the patients prior to treatment. There were 29 examples of group 1 cerebrospinal fluid and 1 example of group 3 according to the criteria of Moore and Mohr.[8] Of this group of 30 patients, 4 had repeat examinations in the six month or one year interval. These revealed two normal spinal fluids and two of the group 1 type. Among the 16 patients with treatment failures 2 had abnormal fluids of the group 1 type before treatment. All the 14 patients with normal pretreatment spinal fluids whose treatment failed were reexamined at the time of failure and showed no evidence of neurorecurrence.

Treatment was known to have failed in 16 of the total patients treated. The failures consisted of 2 examples of relapsing primary syphilis; 5 of primary syphilis progressing to secondary syphilis; 5 of relapsing secondary syphilis and 4 serologic relapses. Three patients were considered to have probable reinfections.

Reactions consisted of local and systemic Herxheimer reactions which were apparent before fever was artificially induced. Eleven of the 120 patients did not complete the prescribed amount of fever and are not included in this report; 8 of these because of lack of cooperation, 2 because of cardiovascular fatigue, and 1 because of uncontrollable fever.[9] All but 1 continued to receive the full amount of penicillin. No serious reactions were noted during or after treatment in any of the 120 patients.

SCHEDULE B

One hundred and ninety patients, exhibiting dark field positive lesions of primary or secondary syphilis, were considered eligible for treatment. One hundred and eighty-eight completed treatment by the following schedule within the period from Dec. 27, 1944 through July 30, 1945. Each patient received 50,000 units of sodium penicillin intramuscularly every two hours for twelve doses beginning at 10 a. m. the day prior to fever (total 600,000 units). Following the twelfth dose, the patient was placed in the "hypertherm" and given six hours of maintained fever at 106 F. (R) level, and at each hour of elevated temperature received 100,000 units of penicillin intramuscularly (600,000 units total). This provided a total dose of 1,200,000 units of penicillin and six hours of fever in approximately thirty hours.

No further treatment was given unless clinical or serologic relapse occurred or pregnancy intervened.

Observation of these patients over a maximum period of twenty-three months and a minimum of sixteen months is presented.

The distribution of patients according to age, sex and race is given in table 3. The age of the patients ranged from 15 to 50 years; 22.9 per cent were under 20 years of age; 44.1 per cent from 20 to 24 years, and 33 per cent over 24. There were 18 (9.6 per cent) cases of primary seronegative syphilis; 35 (18.6 per cent) of primary seropositive syphilis (including 1 reinfection); 128 (68.1 per cent) of secondary syphilis (including 3 reinfections), and 7 (3.7 per cent) cases of relapsing early syphilis.

TABLE 3.—*Patients Treated According to Schedule B: Number and Percentage of Patients Grouped by Race, Sex and Age*

Race and Sex	Age in Years: Number				Percentage			
	Total	Under 20	20 to 24	Over 24	Total	Under 20	20 to 24	Over 24
Total........	188	43	83	62	100.0	100.0	100.0	100.0
Male......	81	9	31	41	43.1	20.9	37.3	66.1

Female...	87	28	44	15	46.3	65.1	53.0	24.2

* Including 1 Japanese.

The results of treatment at designated intervals are summarized in table 4 for the group as a whole, and demonstrated in chart 2 by stage of disease. The statistical device used was identical to the one described earlier in this paper.

All lesions healed immediately after treatment; there was a tendency to require a similar amount of time as those in schedule A, which was a more prolonged form of treatment. The healing of the lesions was comparable, however, if one compared the two groups from the date of initiation of treatment.

TABLE 4.—*Patients Treated According to Schedule B: Results and Number of Days from Beginning of Therapy*

Number of Days from Beginning Date of Therapy	Number of Patients: Total Observed During Period or Later	Serologic Titer: Negative	Serologic Titer: Positive	Failures
0- 29	188	9	179	..
30- 59	174	25	119	..
60- 89	165	42	113	10
90-119	147	51	89	7
120-149	137	57	71	9
150-179	123	61	57	5
180-209	115	64	49	2
210-239	110	63	45	2
240-269	105	66	35	4
270-299	97	66	29	2
300-329	90	61	25	4
330-359	83	60	20	3
360-419	74	62	8	4

Eighty-three (48.8 per cent) of the 170 seropositive patients achieved seronegativity. Nine (10.8 per cent) of the 83 subsequently relapsed. Three patients were retreated because of pregnancy.

Treatment in 52 of the total 188 patients was known to be a failure: There were 4 examples of relapsing primary syphilis; 5 of primary syphilis progressing to secondary syphilis; 18 of relapsing secondary syphilis; 24 of serologic relapses, and 1 neurorecurrence. Four possible reinfections were considered failures.

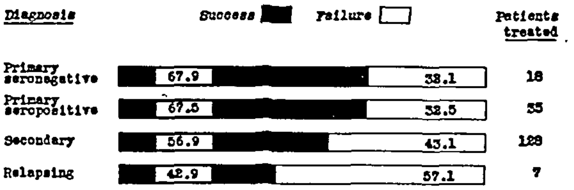

Chart 2.—Percentage of successes and failures by diagnosis at end of first year's observation of 188 patients treated according to schedule B

A lumbar puncture was performed in all but 6 of the patients prior to treatment. There were 32 abnormal spinal fluids of group 1 and 2 of group 3. Of these 34 patients, 16 had repeat examinations from six months to one year later. Seven revealed normal fluids and 9 abnormal; 7, group 1, 1 group 2 and 1 group 3.

Among the 52 whose treatment was a failure, 11 had abnormal spinal fluids before treatment. There were 9 patients with group 1 fluids and 2 with group 3 fluids. Of the 11 patients, 5 showed normal post-treatment fluids and 3 group 1 and one each group 2 and group 3 fluids; 1 patient was not reexamined. Of the 41 patients with normal pretreatment spinal fluids who later relapsed, 30 were normal when reexamined at the time of failure and 2 had group 1 fluids. Nine patients were not reexamined.

Reactions during treatment as in schedule A consisted of local and systemic Herxheimer reactions which were apparent before fever was induced. Eleven patients did not receive the prescribed amount of treatment and are not included in the evaluation, 7 because of lack of cooperation; 2 had hyperpyrexial psychosis but recovered quickly with lowering of the fever, and 2 missed one dose of penicillin, omitted through error. There were no serious reactions in the entire group.

---

[9] Schwemlein, G. X.: The Effect of Elevated Body Temperature on the Cardiovascular System and the Electrocardiogram with Special Emphasis on the Chest Leads, Arch. Phys. Med. 28: 165, 1947.

COMMENT

Comparison of the results of treatment in schedule A.—i. e., 1,200,000 units of penicillin with three sessions of artificial fever with another group who received penicillin alone[10] in the same time-dose relationship makes apparent that the group receiving the additional fever has a lower failure rate. When broken down by diagnosis it is obvious that the groups may not be large enough for tests of statistical significance. However, in the group receiving penicillin alone there are 176 untreated cases of secondary syphilis with a cumulative failure rate of 35.7 per cent, while in schedule A the cumulative failure rate is 12.5 per cent in 64 cases of untreated secondary syphilis. The cumulative failure rate taken regardless of diagnosis is 29.6 per cent in 324 patients receiving penicillin alone and 17.9 per cent in the 109 patients receiving the additional therapeutic fever (chart 3).

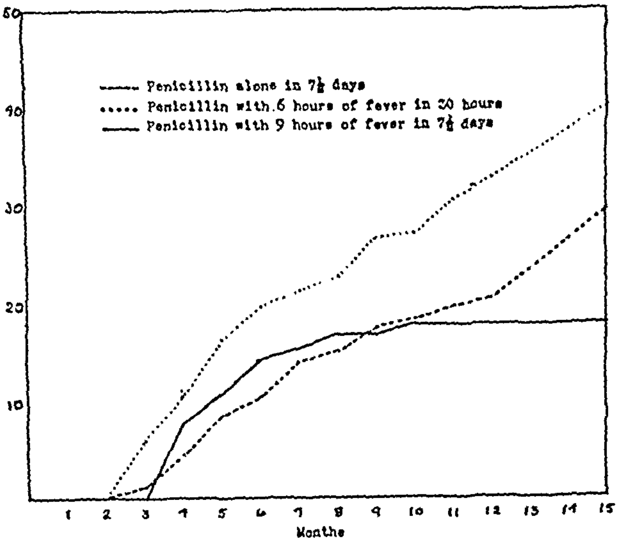

Chart 3.—Cumulative failures for patients treated with 1,200,000 units of penicillin

Schedule B is not as effective as schedule A, as evidenced by the cumulative failure rate of 43.1 per cent among 128 patients with untreated secondary syphilis and 40.1 per cent in the group of 188 patients taken regardless of diagnosis.

In chart 4[11] are shown the cumulative failure rates of the groups receiving fever therapy compared to patients receiving 300,000 units of penicillin in seven and one-half days plus oxophenarsine hydrochloride (0.04 Gm.) daily (51 per cent)[12]; patients receiving 600,000 units in seven and one-half days (40.5 per cent)[9]; 1,200,000 units in three and three-quarter days (25.2 per cent)[13]; 1,200,000 units in seven and one-half days (29.6 per cent)[10]; 10,000,000 units in twenty-four hours (67.8 per cent), and 25,000,000 units in twenty-four hours (35.2 per cent).[14] It is apparent that the group receiving 1,200,000 units of penicillin over seven and one-half days and three 3 hour sessions of fever at 106 F. (rectal) has the lowest cumulative failure rate.

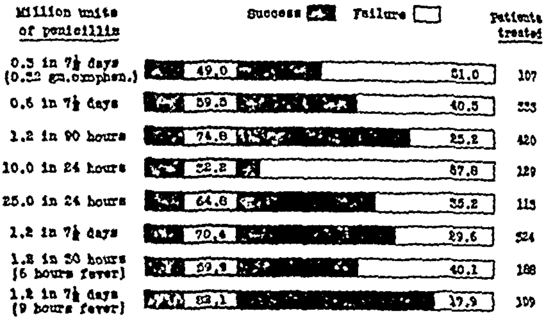

Chart 4.—Percentage of successes and failures at end of first year's observation.

The tendency toward neurorecurrence was not apparent. In the majority of patients examined there was improvement in the abnormal cerebrospinal fluid formulas.

The sodium penicillin used on the fever-penicillin schedules was the same as that used in the group receiving penicillin alone (1,200,000 units in seven and one-half days). The time of administration was, in general the same; i. e., the first six months of the year 1945.

That the fever-penicillin schedules were technically more difficult to administer is not disputed. Furthermore, it was impossible to complete the fever portion of the treatment in some patients who, because of inadequate intelligence, refused to cooperate.

SUMMARY

One hundred and nine patients with dark field positive lesions of early syphilis were given 1,200,000 units of penicillin over seven and one-half days and three sessions of physically induced fever (schedule A). One hundred and eight-eight patients with dark field positive lesions of early syphilis were given 1,200,000 units of penicillin over a period of approximately thirty hours and a single six hour session of fever (schedule B).

The cumulative failure rate in schedule A was 17.9 per cent as compared with 29.6 per cent in a group receiving the same amount of penicillin alone. Attempts to shorten the fever-penicillin treatment to thirty hours were unsuccessful in that the failure rate was 40.1 per cent.

Penicillin and fever therapy given over seven and one-half days produced the lowest cumulative failure rate among patients treated with penicillin in the studies described.

[11] The results presented in this paper must be interpreted in light of the fact that from June 1943, the date of inception of the study, to the present time, commercial penicillin has been a changing mixture of various substances. The content of "impurities" has gradually decreased as potency, in terms of units per milligrams, has increased. The relative amounts of the several identified penicillin fractions, G, F, X and K, have likewise varied from time to time. Those two changes, and perhaps others, suggest that therapeutic efficacy may not have remained constant and that it may be significantly different today than it was originally. It is not now possible to assess the extent to which these changes may have affected the results here reported.

Special Article

This article is the thirteenth of a series to be published by the American Medical Association in cooperation with the American Cancer Society. The series is designed to aid in the early diagnosis of cancer and thereby to gain more effective results in treatment.

CARCINOMA OF THE ESOPHAGUS AND STOMACH

RICHARD H. SWEET, M.D.
Visiting Surgeon, Massachusetts General Hospital
Boston

I. CARCINOMA OF THE ESOPHAGUS

The epochal advances which have been made in the field of thoracic surgery in the past ten years have brought about a new interest in the subject of carcinoma of the esophagus, a disease which until now has been attended by a completely hopeless prognosis. This interest results from the demonstration that in a large number of the cases a resection and intrathoracic esophagogastric anastomosis can be performed. Sufficient experience with the use of this operation has been accumulated to prove that it provides by far the best form of palliation among the patients who will ultimately succumb to the disease, but more important than that is the fact that an appreciable number of patients will survive for three or more years as a result.[1] This operation, therefore, for the first time provides hope that a patient may be cured of this dread disease.

Carcinoma of the esophagus is a common disease. At the Massachusetts General Hospital approximately two thirds as many cases of carcinoma of the esophagus are seen as of carcinoma of the stomach. It has been estimated that there are approximately 40,000 deaths per year in the United States of America because of carcinoma of the stomach. It is reasonable, therefore, to assume that there are about 26,000 to 27,000 deaths per year from carcinoma of the esophagus.

Although they are characteristically of the squamous cell variety, the degree of malignancy of these tumors is of a high order. This is shown by the fact that in over 70 per cent of the patients whose growths are resectable there are already metastases to the regional lymph nodes at the time of operation.[2] Extension of the growth in the wall of the esophagus is often wide, and involvement of the adjacent organs by direct invasion frequently occurs relatively early in the development of the disease. All hope of cure therefore rests on the establishment of an early diagnosis and the prompt resort to surgical extirpation.

DIAGNOSIS

There are three important means of investigation available which when combined should make it possible to establish a positive diagnosis in every case of carcinoma of the esophagus. These are as follows:

1. *Clinical History.*—The onset of the symptoms in carcinoma of the esophagus is almost invariably the same from case to case. The first symptom is dysphagia, often intermittent, depending on the physical properties of the food swallowed. The patient usually chokes first on a large piece of meat. After that experience he is likely to do nothing about it excepting to chew his food more carefully or to avoid eating that which caused the difficulty. In a few weeks, however, he discovers that he is unable to swallow other foods. Bread usually presents the next obstacle. By the time he cannot swallow bread, he finds it necessary to have his meat ground and to eat only soft, nonbulky, solid foods. From then on the transition to the point where he can swallow only liquids is rapid. In the majority of patients the duration of symptoms from the time of onset to the time of first admission to the hospital is six months or less (table 1).

Table 1.—*Duration of Symptoms in Carcinoma of the Esophagus and Cardia (First Symptom to Entry to Hospital)*

	Location of Carcinoma			
	Cardia		Midthoracic Esophagus	
	No. of Cases	Percentage	No. of Cases	Percentage
Less than 3 months	23	22.3	23	36.5
3 to 6 months	37	35.9	16	25.4
6 to 9 months	20	19.4	10	15.9
9 to 12 months	7	6.8	5	7.9
Over 12 months	11	10.7	5	7.9
Not stated	5	4.9	4	6.3
Total	103		63	

In spite of the fact that in carcinoma of the esophagus the duration of symptoms tends to be relatively short, the disease in the majority of cases is already far advanced by the time the patient is seen by the surgeon. This observation on first thought seems difficult to understand because of the fact that the first symptom is the result of obstruction and that the diameter of the

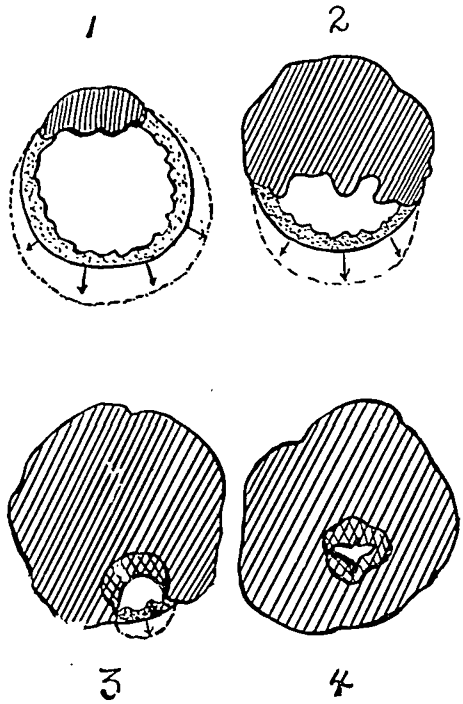

Fig 1.—Diagram representing cross sections through the esophagus at the level of a carcinoma developing in its wall 1. Early stage when there are practically no symptoms 2. Later stage representing the period when large particles may become lodged but with sufficient uninvolved esophagus to permit enough distension for the passage of a fairly liberal soft solid diet. 3 Late stage with almost complete encirclement of the circumference. A narrow strip of uninvolved esophageal wall still allows the passage of liquids. 4. Complete encirclement by tumor with total obstruction. Double-hatched area illustrates the possibility of temporary reestablishment of lumen as a result of necrosis and sloughing of the central portion of the growth.

---

[1] Sweet, R. H.: Carcinoma of the Esophagus and the Cardiac End of the Stomach: Immediate and Late Results of Treatment by Resection and Primary Esophagogastric Anastomosis, J. A. M. A. **135**: 485-490 (Oct. 25) 1947

[2] Sweet, R. H.: Carcinoma of the Midthoracic Esophagus: Its Treatment by Radical Resection and High Intrathoracic Esophagogastric Anastomosis, Ann. Surg. **124**: 653-666, 1946.

esophagus is small. The explanation of the apparent paradox lies in the fact that although the diameter of the esophagus is not large, its wall is very distensible. The result of this is that even though the growth may have involved the circumference of the organ almost completely, there is still enough stretch in the remaining strip of normal esophageal wall to allow the passage of food material through the lumen. It is actually only when the encirclement of the esophagus by the growth is practically complete that the mechanical interference with its function is sufficient to produce a serious degree of obstruction (fig. 1).

Not infrequently after the patient has been almost completely unable to swallow for a period of time, he may experience a sudden release of obstruction so that he can swallow a fairly liberal liquid or soft solid diet again. This results from the necrosis and sloughing of the central portion of the growth so that temporarily at least there is a restoration of continuity along the lumen (fig. 1, no. 4).

Until the end stages of the disease, when complications resulting from distant metastases or local invasion of adjacent organs become manifest, the only other important symptom in carcinoma of the esophagus is pain. It is of two types. The first is the pain which results from local distension or muscle contraction just above the level of the obstructing growth. This is referred to the substernal region with radiation to the back and often to the neck. This pain is of a segmental nature and may be high or low, depending on the level of the tumor in any given case.

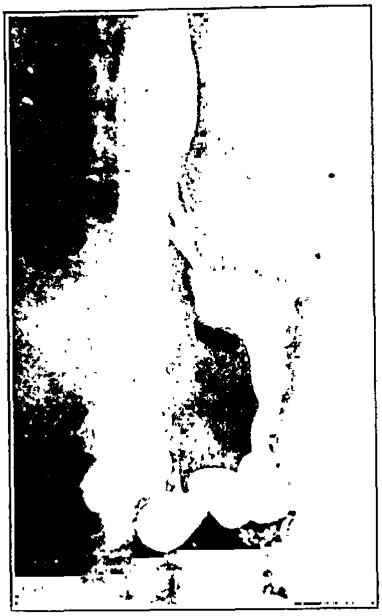

Fig. 2.—Roentgenogram of a carcinoma of the lower fourth of the thoracic portion of the esophagus. Note characteristic encroachment on the diameter of the esophagus with dilatation proximal to the tumor and small stomach below (preoperative roentgenogram).

The second type of pain is a steady, boring, aching discomfort felt deep within the chest and in the back. This is usually the result of periesophageal inflammation from a penetrating ulcerating growth. In some cases it signifies the direct invasion of surrounding structures by tumor or sometimes the presence of metastases to the spine. This type of pain is always of sinister prognostic significance and usually denotes inoperability of the growth.

On the basis of clinical history alone every patient who complains of any disturbance associated with deglutition, whether it be with or without local discomfort, should be given the benefit of further investigation by roentgen studies and often by esophagoscopy in order to determine the presence or absence of a carcinoma of the esophagus.

2. *Roentgen Examination.*—When the disease is well established, there is no difficulty in demonstrating a characteristic irregular filling defect, usually annular in extent, involving the esophagus at whatever level the tumor may be located. The appearance of the shadow seen depends of course on the nature and extent of the tumor. Three different examples, showing both the preoperative and the postoperative roentgen appearances, are presented in figures 2 to 7.

Figure 2 shows the filling defect in the lower portion of the esophagus produced by an advanced epidermoid carcinoma. The relatively long duration of the disease is suggested by the degree of dilatation of the esophagus proximal to the tumor and the small size of the stomach. Figure 3 illustrates the roentgen appearance twelve days after the operation of transthoracic partial esophagectomy and gastrectomy with intrathoracic esophagogastric anastomosis had been performed. In this case it was possible to sever the esophagus low enough so that the anastomosis could be made relatively low in the chest at the level of the inferior pulmonary vein.

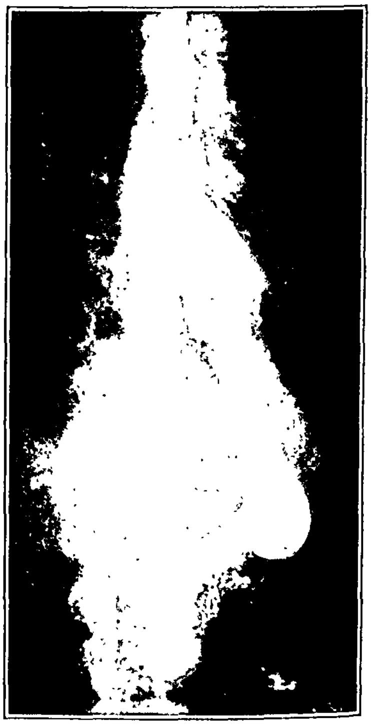

Fig. 3.—Postoperative roentgenogram in case shown in figure 2 after transthoracic partial esophagectomy and gastrectomy. Intrathoracic esophagogastric anastomosis slightly below the level of the left main bronchus which is seen clearly on the film. Actual level is opposite the inferior pulmonary vein.

Figure 4 is a reproduction of the roentgen appearance in a case of carcinoma situated slightly higher in the esophagus than in the case shown in figure 2. The same sort of operation was performed in this case, but the higher level of the growth made it necessary to perform the anastomosis just below the arch of the aorta. This is clearly shown in figure 5, which shows the postoperative roentgen appearance.

A case of carcinoma of the esophagus situated at a much higher level is illustrated by figure 6, which shows the roentgen shadow after the ingestion of barium, with an obvious filling defect situated just behind the aortic arch. At operation in a case of this sort it is necessary to displace the esophagus from behind the aortic arch and to pull the completely mobilized stomach up to the apex of the left pleural cavity for a high supra-aortic esophagogastric anastomosis. The postoperative appearance in such a case is shown in figure 7, which illustrates the location of the anastomosis at the level of the suprasternal notch.

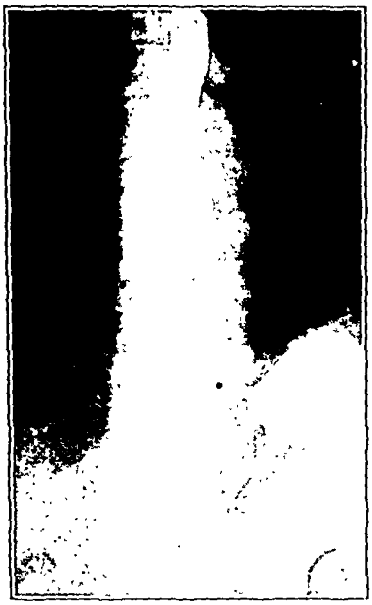

Fig. 4.—Roentgenogram of a carcinoma in the lower portion of the middle half of the esophagus showing a short length of normal esophagus below the growth and a characteristic irregular annular filling defect (preoperative roentgenogram).

From the standpoint of prognosis or even the prediction of resectability the roentgen examination cannot be relied on to be completely accurate. But in general, the larger the filling defect and the greater its longitudinal extent in the esophagus, the more likely is the growth to be inoperable. Every patient, however, should be given the benefit of an exploration if his age and general condition will permit.

If the growth happens to be an early one, on the other hand, its presence may not be detected during the fluoroscopic examination and as a result many weeks of delay ensue. The relative number of cases which are detected bears a direct relation to the skill and interest of the roentgenologist. The physician in charge of such a patient should make it clear that he suspects the presence of an esophageal lesion. If this is not done, the attention of the roentgenologist is likely to be directed toward the stomach and duodenum after a cursory routine observation of the descent of the barium through the esophagus. In general the number of cases in which at least a suggestive diagnosis of carcinoma of the esophagus cannot be made by roentgen examination is exceedingly small. If the findings of the roentenologist are negative or misleading in any case in which the clinical history suggests the presence of an esophageal lesion, direct inspection through an esophagoscope is mandatory.

3. *Esophagoscopic Examination.*—By means of the esophagoscope a positive diagnosis of carcinoma of the esophagus can be established in a large percentage of the cases. The direct visualization provided by this means makes it possible for an experienced observer to recognize the presence of a pathologic area and to obtain tissue for histologic study. It should be remembered, however, that even in the case of a suspicious-looking lesion the examination of material obtained for a biopsy may be negative for carcinoma because of the fact that the grasp of the biopsy forceps was not deep enough. In this way nothing but chronic inflammatory tissue is obtained from the inflammatory area which usually surrounds an infected ulcerated malignant lesion, although a deeper bite of the forceps would reach the tumor tissue. A repetition of the esophagoscopic examination may therefore be necessary. In some such cases it is wiser to proceed with a surgical exploration than to wait until the biopsy becomes positive because of the obvious undesirability of postponing the extirpation of the growth.

TREATMENT

The treatment of carcinoma, in no matter what organ it may arise, should be calculated not only to bring about a cure in the favorable cases, but also to provide the maximum relief of discomfort in the relatively larger group of patients whose disease is beyond the hope of cure. In carcinoma of the esophagus for many years there was little or no hope for cure and a poor prospect for relief of suffering. The failure of roentgen treatment to measure up to the aforementioned ideal of treatment is well known. Few patients treated by this means have been made to live much longer than those who were not treated, although in a small percentage of patients temporary improvement in the ability to swallow has resulted. Bougienage in an attempt to keep a passageway open is disappointing because of the impossibility of applying the method in many cases and the transitory benefit obtained when it has been used.

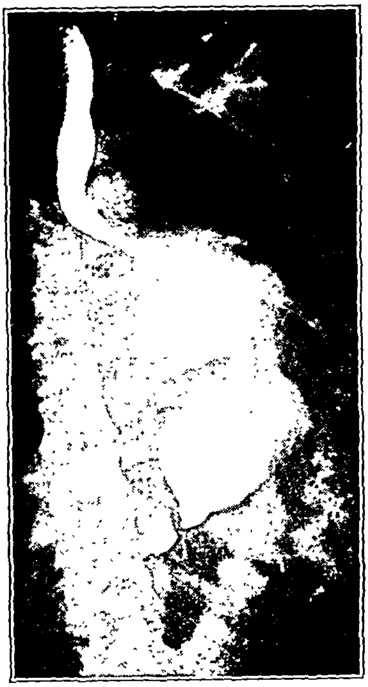

Fig. 5.—Postoperative roentgenogram in case shown in figure 4 after transthoracic partial esophagectomy and high intrathoracic esophagogastric anastomosis. The anastomosis lies just below the arch of the aorta.

The only hope of cure in the favorable cases and the best prospect of relief among patients who ult mately succumb to the disease is provided by the application of surgery. As a result of vast improvements in this field the operation has been developed to the point where a reasonable outlook for cure and a far better degree of palliation than was ever available before can now be offered to patients who are afflicted with the disease. In this connection mention should be made of the Torek operation, which was first described in 1913.[3] It provides for a limited excision of the tumor-bearing segment of the esophagus but not for the removal of a sufficient number of the regional lymph nodes. As a cancer operation, therefore, it cannot be expected to make possible a large percentage of long survivals among the patients treated (table 2). Furthermore, it is an ineffectual palliative procedure because of the discomforts of the cervical esophagostomy stoma and the annoyance of having to use a gastrostomy opening for feeding. In a few cases an external esophagoplasty can be performed, but only after a many stage plastic procedure which is often not completed before the patient dies of metastases or recurrent disease.[4]

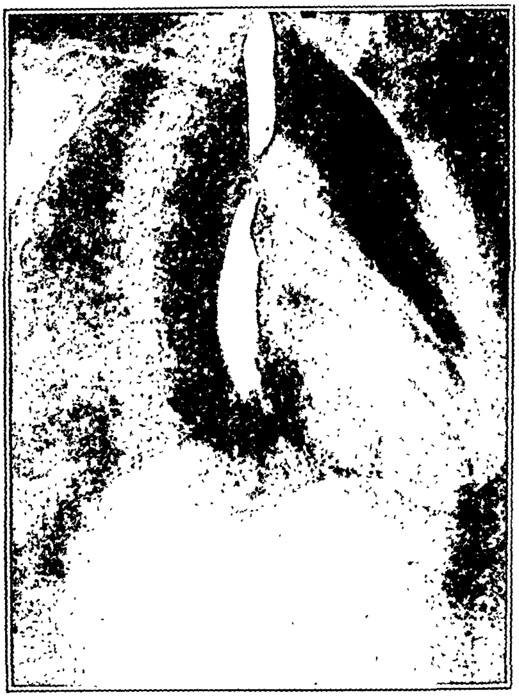

Fig. 6.—Roentgenogram of a carcinoma of the esophagus located behind the aortic arch (preoperative roentgenogram). Note the short distance between the upper margin of the growth and the level of the clavicle. This type of case requires the performance of an anastomosis at the highest possible level within the chest.

* Holmes, G. W., and Schulz, M. D.: Supervoltage Radiation: A Review of the Cases Treated During an Eight Year Period (1937-1944 inclusive), Am. J. Roentgenol. 55: 533-534, 1946.

Because of these inadequacies, the Torek operation has been discarded in favor of the operation of transthoracic resection of the growth with a primary intrathoracic esophagogastric anastomosis. By this means a tumor even as high in the esophagus as the level of the aortic arch can be successfully removed and an immediate restoration of the continuity of the alimentary canal can be established. It has been found that such a resection can be performed in approximately 65 per cent of the patients operated on.[1] The operative mortality of 9.5 per cent (lower end) to 24 per cent (level of aortic arch) is by no means prohibitive in consideration of the hopelessness of the disease. It has been shown likewise that of those who have survived the operation, 39.1 per cent of the patients whose operation was performed three or more years before the date of the follow-up study have lived for three or more years (table 2).

Furthermore, as a palliative procedure the operation of resection and intrathoracic esophagogastric anastomosis is the best method of treatment yet available, because the majority of those who ultimately succumb to the effects of the disease do not have recurrence at the site of anastomosis. The result is that they continue to eat in a normal fashion as long as they may live.

PROGNOSIS

As with carcinoma elsewhere, the ultimate prognosis in carcinoma of the esophagus depends on the duration and extent of the disease. It is obvious, therefore, that to obtain a favorable result surgical excision must be carried out at the earliest practicable moment. The attainment of this ideal depends on the prompt application of the patient to his physician for relief, the alertness of the physician to the possibility of the presence of such a growth, the ability of the roentgenologist to suggest the probable presence of a carcinoma and of the endoscopist to prove it by biopsy, and, finally, the willingness of the surgeon to perform the proper operation.

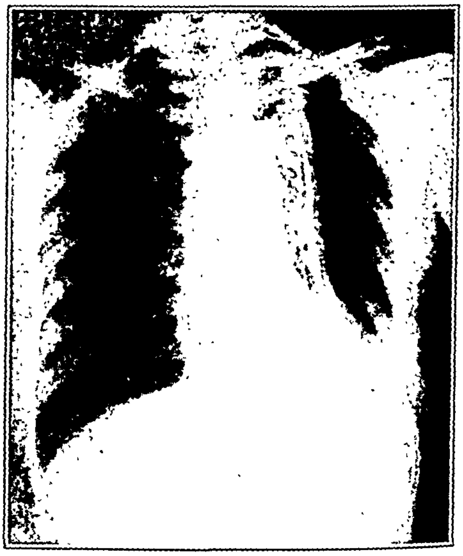

Fig. 7.—Postoperative roentgenogram of the case shown in figure 6 after transthoracic subtotal esophagectomy and high esophagogastric anastomosis. The anastomosis lies above the level of the aortic arch and behind the suprasternal notch.

II. CARCINOMA OF THE STOMACH

Unlike carcinoma of the esophagus, which has only recently been shown to be curable by the prompt application of surgery, carcinoma of the stomach has long been the practical concern of the surgeon. Although the early efforts of the pioneers in the field of abdominal surgery were discouraging because of the high operative mor-

This type of case requires the performance of an anastomosis at the highest possible level within the chest.

TABLE 2.—*Comparison of the Results of Treatment of Carcinoma of the Esophagus by Several Methods*

	Percentage of Survival 3 or More Years
No treatment	0
Roentgen treatment *	0
Torek operation	8.3
Resection and anastomosis	39.1

* Holmes, G. W., and Schulz, M. D.: Supervoltage Radiation: A Review of the Cases Treated During an Eight Year Period (1937-1944 inclusive), Am. J. Roentgenol. 55: 533-551, 1946.

Because of these inadequacies, the Torek operation has been discarded in favor of the operation of transthoracic resection of the growth with a primary intrathoracic esophagogastric anastomosis. By this means a tumor even as high in the esophagus as the level of the aortic arch can be successfully removed and an immediate restoration of the continuity of the alimentary canal can be established. It has been found that such a resection can be performed in approximately 65 per cent of the patients operated on.[4] The operative mortality of 9.5 per cent (lower end) to 24 per cent (level of aortic arch) is by no means prohibitive in consideration of the hopelessness of the disease. It has been shown likewise that of those who have survived the operation, 39.1 per cent of the patients whose operation was performed three or more years before the date of the follow-up study have lived for three or more years (table 2).

Furthermore, as a palliative procedure the operation of resection and intrathoracic esophagogastric anastomosis is the best method of treatment yet available, because the majority of those who ultimately succumb to the effects of the disease do not have recurrence at the site of anastomosis. The result is that they continue to eat in a normal fashion as long as they may live.

PROGNOSIS

As with carcinoma elsewhere, the ultimate prognosis in carcinoma of the esophagus depends on the duration and extent of the disease. It is obvious, therefore, that o obtain a favorable result surgical excision must be carried out at the earliest practicable moment. The attainment of this ideal depends on the prompt application of the patient to his physician for relief, the alertness of the physician to the possibility of the presence of such a growth, the ability of the roentgenologist to suggest the probable presence of a carcinoma and of the endoscopist to prove it by biopsy, and, finally, the willingness of the surgeon to perform the proper operation.

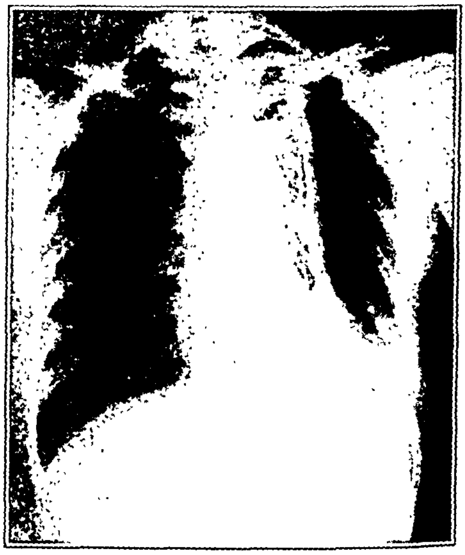

Fig. 7.—Postoperative roentgenogram of the case shown in figure 6 after transthoracic subtotal esophagectomy and high esophagogastric anastomosis. The anastomosis lies above the level of the aortic arch and behind the suprasternal notch.

II. CARCINOMA OF THE STOMACH

Unlike carcinoma of the esophagus, which has only recently been shown to be curable by the prompt application of surgery, carcinoma of the stomach has long been the practical concern of the surgeon. Although the early efforts of the pioneers in the field of abdominal surgery were discouraging because of the high operative mortality and the inadequacy of the resection, it has been known for many years that carcinoma of the stomach is curable in a reasonably large number of cases. In recent years, as a result of earlier diagnosis, lower operative mortality and a widening of the scope of the operation, the number of patients who are presumably cured has been increased to an appreciable extent. The latest reports from various clinics have shown that of the patients who are operated on from 20 to 30 per cent will survive five years or more.[5] Pack and McNeer[6] have shown that of the patients in their series who were subjected to resection approximately 35 per cent survived five years or more.

---

[3] Torek, F.: The First Successful Resection of the Thoracic Portion of the Esophagus for Carcinoma, J. A. M. A. 60: 1533 (May 17) 1913.

[4] Sweet, R. H.: Surgical Management of Carcinoma of the Midthoracic Esophagus, New England J. Med. 233: 1-7, 1945.

In spite of this relatively encouraging outlook there is a widespread pessimism among physicians at large regarding the results of surgical treatment. This impression can hardly be avoided when one reflects on the over-all prospects of the disease as observed in the population as a whole. Statistical studies from various sources show that of all patients with proved carcinoma of the stomach, not over 5 per cent survive five years or more and then only as a result of the application of surgery. To be influenced by this apparently discouraging result, however, is to place emphasis on the wrong aspect of the problem. The fact that, of all cases of carcinoma of the stomach in which a diagnosis has been made, in only 5 per cent a cure is effected, indicates that a large percentage of the cases are unsuitable for surgery when the patient is first seen or too far advanced for cure even though surgical excision is attempted. There are innumerable statistics to prove this contention. The latest reports show that at least 25 per cent of the cases seen are unsuitable for operation because of the far advanced state of the disease. Furthermore, even in the hands of the most experienced surgeons only 50 per cent of the total number of cases seen are actually suitable for resection These data are a reflection of the well known fact that in a large percentage of the cases the diagnosis is made late in the course of the disease. The explanation of this unfortunate situation lies partly in the fact that the onset of the disease is often insidious and partly in the neglect of the patient to seek relief at an early date or the failure of the physician to suspect the presence of the disease and to take the necessary steps to establish a diagnosis.

DIAGNOSIS

In the advanced stages of the disease with emaciation, anemia, anorexia, asthenia and perhaps the presence of a palpable tumor in the upper part of the abdomen, the diagnosis of carcinoma of the stomach is usually suspected and readily proved To establish the diagnosis in such cases, however, is obviously of little importance because of the improbability of cure. Emphasis should be placed on the early detection of the disease The following discussion will therefore be confined to the problem of discovering such cases at a time when surgery may be expected to provide some prospect of cure.

1. *Clinical History and Physical Findings*.—The first obstacle in the way of establishing an early diagnosis in cases of carcinoma of the stomach lies in the fact that the onset is so often insidious and the early symptoms so vague and obscure. Anorexia and asthenia of slight degree in the absence of any other complaints comprise the first symptoms in approximately 20 per cent of the cases. This type of onset is particularly frequent in growths located in the middle segment of the stomach. Vague dyspeptic symptoms which are spoken of as "discomfort," "distress," "indigestion" or a "bloated or full feeling" after eating are mentioned by about 20 per cent of the patients. Another 25 per cent of the patients complain of definite pain occurring soon after the ingestion of food. In cases in which the tumor happens to lie close to the pylorus such pain may be a prominent early symptom and vomiting may follow after a relatively short lapse of time because of the small diameter of the lumen at that point. If the growth happens to start near the cardia, early involvement of that orifice leads to dysphagia and prompt regurgitation of ingested food.

Bleeding from gastric carcinoma is usually of a chronic nature and is rarely discovered except by the finding of a positive reaction to a test for occult blood in the vomitus or stools. Occasionally, however, massive hematemesis may occur (not over 1 per cent of cases), but it is not often an early sign of the disease.

Objective findings such as evidences of loss of weight, hypochromic anemia and the presence of occult blood in the stools or gastric contents have no specific diagnostic significance That the difficulty may lie in the stomach is strongly suggested, however, by the additional observation of achlorhydria of the gastric contents. This occurs in approximately 70 per cent of all patients with gastric carcinoma and, when associated with suggestive signs or symptoms, should lead to a strong suspicion of the presence of that disease. That gastric carcinoma can occur in the presence of a normal concentration of hydrochloric acid is also well known. The presence of acid in the gastric contents should therefore never be allowed to militate against the making of a diagnosis of carcinoma of the stomach if other aspects of the case suggest it.

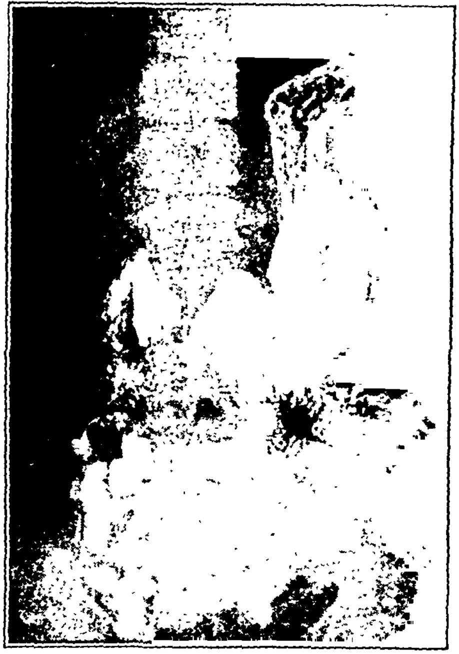

Fig. 8.—Roentgenogram of a large carcinoma involving the majority of the body and fundus of the stomach Total gastrectomy is required to remove all the growth.

2. *Roentgen Examination*.—Without question the most valuable method of investigation in cases of suspected carcinoma of the stomach is the fluoroscopic study of the behavior of the stomach after the ingestion

---

[5] Wangensteen, O H. The Problem of Gastric Cancer, J. A. M A **134**: 1161-1169 (Aug. 2) 1947.

[6] Pack, G. T., and McNeer, G, in discussion on Wangensteen.[5]

of a barium meal and the demonstration by roentgenograms of the presence of a persistent filling defect in the gastric shadow. The characteristic findings have been described so frequently that they need not be set forth here. Figure 8 serves to illustrate a classical example of the roentgen appearance of a case of carcinoma of the body and fundus of the stomach. This patient was operated on successfully. A reproduction of the postoperative roentgen appearance is given in figure 9, showing the appearance of the anastomosis after the performance of a total gastrectomy.

In spite of the excellence of the method, however, it is not realized universally that the accuracy of roentgen studies in the establishment of a positive diagnosis of carcinoma of the stomach does not exceed 90 per cent in the best of hands.[7] In some cases, therefore, additional aid in making a diagnosis is necessary. This may be obtained by the use of the gastroscope or in some cases the esophagoscope.

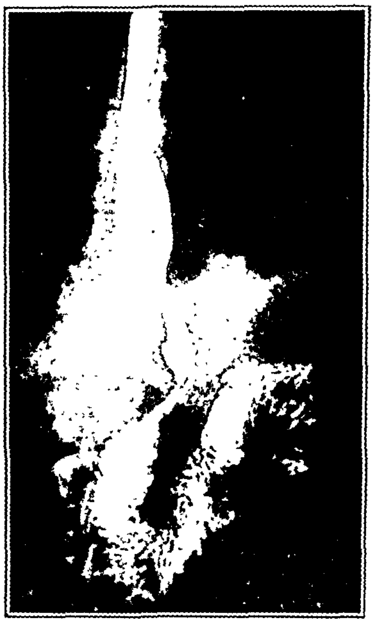

Fig. 9.—Postoperative roentgenogram of case shown in figure 8 following total gastrectomy with restoration of the continuity of the alimentary canal by esophagoduodenal anastomosis (restoration of continuity after total gastrectomy is usually by an esophagojejunal anastomosis; in certain favorable cases, however, it is possible to use the duodenum for an end to end anastomosis with the esophagus) The operation was performed by the transthoracic approach.

3. *Endoscopic Examination.*—Direct inspection of the interior of the stomach by means of a gastroscope is a useful adjunct to the roentgen investigation in a few cases in which carcinoma of the stomach is suspected. The interpretation of the observations depends on the experience of the observer and on the location of the lesion. Lesions of the stomach located in certain areas, notably the fundus, cannot be seen readily through a gastroscope. In the body and antrum, however, the method is most useful and in some cases has been the means of demonstrating the actual presence of a carcinoma which may not have been visualized by the use of roentgen methods even though it had been suspected on the basis of the history and physical examination. The limitations of the gastroscope are such, on the other hand, that, although the lesion may be seen, a specimen cannot be obtained for biopsy purposes.

In certain cases in which the growth lies at the cardia or in the fundus of the stomach, it can be seen best through the esophagoscope. In such cases, because of the construction of the instrument, a piece of tissue can usually be obtained for histologic confirmation of the diagnosis.

Occasionally peritoneoscopy is of value, not so much to prove the presence of a growth in the stomach as to detect the presence of metastases in the liver or elsewhere throughout the abdominal cavity. This procedure is therefore of relatively little importance as an aid to the establishment of an early diagnosis in gastric carcinoma. It serves rather as a method of predicting the operability or possible curability in the more advanced cases.

4. *Cytologic Examination.*—A new method in the field of diagnosis in carcinoma of the stomach is the cytologic examination of the gastric contents as set forth by Papanicolaou[8] and others. This involves the study of a stained specimen obtained from the sediment of the fluid aspirated out of the stomach. The success of its application depends on the knowledge and experience of the technician who may be called on to express an opinion on the basis of an examination of the smear. In the hands of an experienced person, however, characteristic tumor cells can be demonstrated, and in some cases a definite diagnosis of carcinoma can be made. As more experience is accumulated, this method gives promise of greater usefulness in the confirmation of a diagnosis of carcinoma of the stomach. It may also become a useful means of detecting early cases in which there is only a reasonable suspicion on the basis of the history, roentgen studies and endoscopic observation of the presence of the disease.

5. *Exploratory Operation.*—The importance of an early diagnosis and the prompt removal of the growth in gastric carcinoma is such that surgical exploration should be used in every suspected case when other diagnostic methods prove inconclusive. This is important not only in all suspected cases, but also in all cases of gastric ulcer which is presumed to be benign but which does not heal after a reasonable period of observation. The danger of treating an early ulcerating carcinoma of the stomach as though it were a benign ulcer because of the roentgen appearance, the possible absence of achlorhydria or even the opinion of the endoscopist is so great that the majority of experienced surgeons and internists agree that in every case of gastric ulcer which does not heal completely within a short period of time (one month at the utmost) resection should be done as though it were a proved case of gastric carcinoma. Only in this way will the outlook of the patient be safeguarded and the physician preserved from embarrassment in certain cases, many of which will inevitably turn out to be early enough to be cured.

TREATMENT

As in carcinoma of the esophagus, the only prospect of cure in carcinoma of the stomach results from a total extirpation of the growth by surgical means. This may involve the removal of the lower half or more of the stomach through an abdominal incision, the extirpation of the proximal half or more of the stomach through a transthoracic or abdominothoracic approach, or the performance of a total gastrectomy by either the abdominal or the transthoracic route. The exact details of the technic and the choice of procedure to be employed must depend on the location and extent of the growth in the stomach and on the judgment of the surgeon. As with carcinoma everywhere, the fundamental principle to be observed in all cases in which there is a reasonable hope of cure is to remove the tumor-bearing portion of the stomach with as large a margin of apparently normal stomach as seems practicable, along with the regional lymph nodes and the great omentum.

PROGNOSIS

All that was said regarding the factors which influence the prognosis in cases of carcinoma of the esophagus applies to the situation in gastric carcinoma. Early diagnosis and prompt radical surgery provide the only hope for the patient. But because of the much longer period of time during which extirpation has been practiced in the treatment of carcinoma of the stomach, it is possible to make useful predictions regarding the prospects of patients with the disease based on surgical experience and the correlation between end results and the pathologic characteristics of the growth. As pointed out by Welch [9] an excellent prognosis for cure can be made in cases of carcinoma in situ or in growths which are of a polypoid nature. A fair prospect can be assumed for patients with an adenocarcinoma or a colloid adenocarcinoma or in any patient who is found to have no metastases in the regional lymph nodes. A poor prognosis must be made in case the tumor is of a signet ring cell type or in cases of histologically undifferentiated tumors. The same is true in all cases in which lymph node metastases are found or when the growth in the stomach is adherent to other viscera, both evidences of a long duration or a high degree of malignancy of the tumor. It has been observed by Welch that if lymph nodes which are obviously invaded by tumor are left behind, the average duration of life is eight months. This observation provides further support for the insistence of all surgeons who may be called on to treat patients with carcinoma of the stomach that the earliest possible diagnosis must be made if the surgical removal of the growth is to prove effective.

On the other hand, even though the diagnosis may be made early in the course of the disease, the outlook for the patient afflicted with carcinoma of the stomach depends on the histologic type of growth which he may happen to have. Table 3, which is adapted from the report of Welch, serves to emphasize the importance of this fact. From this it will be seen that the prospect varies from almost 100 per cent cure in carcinoma in situ to no five year survivals in the case of the signet ring type or an undifferentiated growth. The most frequent histologic type is the adenocarcinoma.

TABLE 3.—*Five Year Survival Rate of Carcinoma of the Stomach According to the Histologic Type* *

	Percentage of Patients Operated On
Carcinoma in situ	90+
Polypoid carcinoma	75
Adenocarcinoma	40
Colloid adenocarcinoma	40
Signet ring (pure colloid) carcinoma	0
Undifferentiated carcinoma	0

* Massachusetts General Hospital statistics [9]

Although the results of treatment of carcinoma of the stomach may leave much to be desired, it is obvious that they are now much better than they were even ten years ago. It is time, therefore, to abandon the old attitude of hopelessness and to accept the present day realization of the fact that, given an early diagnosis and a reasonably favorable pathologic type of growth, carcinoma of the stomach can be cured in an appreciable number of cases.

Clinical Notes, Suggestions and New Instruments

THROMBOPENIC PURPURA FOLLOWING QUINIDINE

PHILLIP L. NUDELMAN, M.D.
IRVING L LEFF, M.D.
and
Clifton D. Howe, M.D.
New York

Thrombopenic purpura following the administration of quinine occurs occasionally,[1] but thrombocytopenic purpura following the use of its optical isomer quinidine is, apparently, extremely rare. The only case in the literature is one concerning a 27 year old woman who during a second course of quinidine sulfate therapy had hemorrhages in the skin and gingival bleeding after taking a total dose of approximately 8 Gm. of the drug.[2] When the patient had completely recovered, the clinical and hematologic picture was reproduced by the administration of one dose of 0.4 Gm of quinidine sulfate

We wish to report another instance of this idiosyncrasy to the drug.

REPORT OF CASE

An Italian-born seamstress aged 57 years with hypertensive and rheumatic heart disease was admitted to this hospital Aug. 1, 1947, complaining of dyspnea of two weeks' duration and frequent attacks of paroxysmal tachycardia over many years. There was no history of allergy, bleeding tendency or previous quinidine therapy. She had had widespread tuberculosis of bone in childhood and rheumatic fever at the age of 20.

On admission the patient was in moderate congestive heart failure. She was digitalized and discharged three weeks later on a maintenance dose of 0.1 Gm. daily. On September 1 she was readmitted complaining of frequent attacks of palpitation which were shown electrocardiographically to be bouts of supraventricular tachycardia. Digitalis was discontinued, and on September 20 quinidine sulfate was begun in a dosage of 0.2 Gm. three times daily. She suffered no further attacks and was discharged September 28 on a maintenance dose of 0.6 Gm. daily.

On October 1, after a total dose of 6.0 Gm. of the drug had been taken, spontaneous bleeding from the gums developed, and the patient was readmitted. On physical examination she displayed, in addition to the gingival bleeding, petechiae in both conjunctivas and widespread purpura of the trunk and limbs. The temperature was 99 F, pulse rate 88, and blood pressure 150 systolic and 60 diastolic. The spleen, not felt on previous admissions, was palpable 2 fingerbreadths below the costal margin. The result of the tourniquet test for capillary fragility was strongly positive. The bleeding time (finger prick) was over 30 minutes; coagulation time (Lee-White) 7 minutes; clot retraction, none in 3 hours, and the prothrombin time was normal. The platelet count (oxalated venous blood) was 4,000 per cubic millimeter. The blood count revealed 4,700,000 red blood cells, 13 Gm. of hemoglobin and 8,300 white blood cells with a normal differential count. A sternal marrow aspiration showed cellular marrow with a normal differential count and with megakaryocytes present and normal in number and appearance. A transfusion of 500 cc. of three day old citrated blood was begun. Five hours later, seventeen hours after its beginning, the mouth bleeding stopped. Subsequent

Maritschek, M., and Markowicz, H.: Ueber einen Fall von Chinenuberempfindlichkeit mit Purpura, vorwiegend der oberen Luft and Speiseweg, Monatschr. Ohrenh. 67:410-414 (April) 1933. Peshkin, M. M., and Miller, J. A.: 102:1737-1740 (May 26) 1934.

[2] Broch, O. J.: Thrombocytopenic Purpura After Administration of Quinidine. Nord. med. 10:1542-1544 (May 17) 1941.

platelet counts were: October 4, 14,000; October 6, 36,000; October 8, 152,000, and October 16, 187,000. On the third day the tourniquet test became negative in result and the bleeding time returned to normal. Two blood cultures were sterile.

Since quinidine might clearly be the drug of choice for future use it seemed wise to make certain that the clinical impression that the drug was responsible for the bleeding was correct. Therefore, after complete recovery from the bleeding episode, a test dose of 0.1 Gm. quinidine sulfate was given by mouth. The developments were striking. At the end of one hour the platelets dropped to 17,000 per cubic millimeter, in two hours to 3,000 and in three hours to 1,000. At this time bleeding from the gums began, followed by profuse bleeding from the nose, and the appearance of widespread purpura of the trunk and limbs as before. Six hours after the test dose the platelets fell to zero. The patient was given 500 cc. of three day old citrated blood. All bleeding ceased completely twenty-one hours after the test dose and within seven days the platelet count, tourniquet test, clot retraction and bleeding time returned to normal.

SUMMARY

A case of thrombopenic purpura secondary to quinidine sulfate is reported. The patient gave no history of previous quinidine therapy. The bleeding episode developed after 6 Gm. of the drug had been taken. An almost identical episode was induced by the administration of a test dose of 0.1 Gm. of the drug.

Council on Foods and Nutrition

This paper, prepared at the request of the Council on Foods and Nutrition, is one of a series which will appear in THE JOURNAL. The entire series will appear later in book form as the Council's Handbook of Nutrition.

JAMES R. WILSON, M.D., *Secretary.*

FAT IN NUTRITION

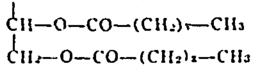
H. C. ECKSTEIN, Ph.D.
Ann Arbor, Mich.

Man through his evolutionary changes has developed into an animal whose gastrointestinal tract has been modified to such a state that considerable portion of fat is desirable in his diet. Although a certain amount of bulk is recognized as being of value in a complete diet, there are limits to which this should be extended. When the bulk of the diet is increased by the incorporation of considerable amounts of carbohydrate, discomforts which are ascribed to abnormal fermentation in the gut are encountered. McClendon,[1] in his investigation of the dietary habits of the Japanese, was impressed by the prevalence of "dyspepsia" in that population and believed that the incapacitation which occurred for comparatively long periods was undoubtedly due to the high carbohydrate diet. The bulk of the diet can be significantly decreased by the incorporation of additional fat, because this foodstuff supplies more than twice the number of calories available from equivalent amounts of protein or carbohydrate. Unlike the other organic dietary substances, fats are almost water free, and this also leads to a decrease in the bulkiness. Starling[1] pointed out that the human alimentary tract is so constructed that it is desirable to include from 20 to 25 per cent of the calories in the form of fat. The desirability of fat in the diet was illustrated during the first great war by the experience of the German population, which regarded the low daily fat allotment as one of their most serious deprivations. It is common knowledge that a meal containing insufficient amounts of fat lacks in the so-called staying powers. Starling[1] illustrated this by the complaints, during the latter stages of the first world war, of laborers that their rations were inadequate to work their normal shifts because of the low fat content. Hunger was the universal reaction. From a biologic point of view, it is recognized that fats are absorbed at a slower rate than carbohydrate, and, in addition, reduce the rate of discharge of gastric contents. The latter effect is ascribed to the inhibitory action of the hormone enterogastrone, the formation of which, in the intestine, is accelerated by the presence of fat.

The animal organism is well adapted to assimilate comparatively large amounts of fat. Cowgill[2] has recently reviewed the subject. Langworthy[3] studied the digestion and utilization of a considerable number of plant and animal fats by healthy adults and observed no notable variations between the behavior of the different types. The daily consumption ranged from 50 to 100 Gm. These observations and others led Cowgill to the following summation: "Edible fats the melting points of which are not too high to prevent liquefaction in the alimentary tract are digested and absorbed to about the same degree. Such differences as have been found are of no practical nutritional significance."

The influence of physical properties on the utilization of fat is well illustrated in the coefficients of digestibility of natural fats hardened to various extents by hydrogenation. Holmes and Deuel[3] observed that the degree of utilization of such products decreased significantly with the rise in melting point. The melting point of fats is to a considerable extent dependent on the chemical nature of the constituent acid radicals in the fat (triglyceride) molecule. Such fats are readily hydrolyzed in the presence of excess hydroxyl ions or specific enzymatic catalysts with the liberation of one molecule of glycerol and three of fat acids. The term " fat acids has recently been introduced to designate the acids originating from natural fats.

In general, the acids in the fat molecule differ from one another and the term "mixed glyceride" is employed to characterize this type of lipid. This is illustrated in the following formula:



$$\begin{array}{l} CH_2-O-CO-(CH_2)_x-CH_3 \\ | \\ CH-O-CO-(CH_2)_y-CH_3 \\ | \\ CH_2-O-CO-(CH_2)_z-CH_3 \end{array}$$

The values for x, y, and z are even numbers ranging from 2 to more than 20. As a rule the chief acidic constituents of the fats in the depots and tissues of mammals contain from 16 to 18 carbon atoms. It does not seem necessary to detail a listing of the numerous fat acids that have been isolated from natural sources, since that information is readily available in standard texts of biochemistry. It should be sufficient to call attention to the fact that fat acids fall into two distinct groups, the saturated type, most representatives of which are solid at room temperature, and the unsaturated class, all members of which are liquid at this temperature. Both groups belong to the same homologous aliphatic series. Quantitatively, palmitic acid, a saturated acid with 16 carbon atoms, and oleic acid, with 18 carbon atoms and 1 unsaturated double bond, predominate in the depot fat of man. Stearic acid, the saturated acid which contains 18 carbon atoms, is occasionally present in considerable amounts in animal depot fat, and when this occurs the melting point of the mixture rises. When oleic acid is hydrogenated, a product identical with natural stearic acid is produced. Vaccenic acid, an isomer of oleic acid, also gives rise to stearic acid when hydrogenated. Two additional unsaturated acids, linoleic and linolenic, occur in abundance in certain culinary fats of plant origin. Both belong to the C-18 series, the former containing two, the latter three double bonds, and each in turn can be transformed into stearic acid on complete hydrogenation. Fish oils contain comparatively large amounts of acid of higher molecular weight with additional double bonds.

[3] Cited by Cowgill.[2]

Culinary fats, while they are characterized by the presence of predominating amounts of the triglycerides (more than 95 per cent), also contain small amounts of the more complex lipids and usually some of the fat-soluble vitamins and pigments. These complex lipids fall into three divisions, the phospholipids, the glycolipids (also designated as cerebrosides), and the sterols. The majority of the phospholipids are closely related to the triglycerides in so far as glycerol is obtained on hydrolysis, but only two fat acids are liberated. The third hydroxyl group of the glycerol molecule is joined to a phosphoric acid linkage, which, in turn, is conjugated with a nitrogenous product. Three such phospholipids have been characterized: lecithin, in which the nitrogenous base, choline, is present, cephalin, containing aminoethyl alcohol, and phosphotidyl serine, in which the nitrogenous constituent is the amino acid serine of wide distribution in the proteins. It is to be noted that in these lipids the ratio of nitrogen to phosphorus is 1 : 1. In contrast, an entirely different type of phospholipid, sphingomyelin, occurs in nature. This contains no glycerol, 1 mole of phosphoric acid, and two nitrogenous fractions, choline and sphingosine. The latter, an unsaturated amino alcohol of high molecular weight, also occurs in the glycolipids, which, in addition, yield 1 mole of fat acid and one simple sugar (galactose or glucose) on hydrolysis. Even more complex glycolipids, the gangliosides, have been described. These contain 1 mole of fat acid, two or three of the simple sugars and an additional nitrogenous product which has not yet been structurally characterized.

The sterols, alcohols of high molecular weight, belong to a group of compounds, the steroids, which include the bile acids, sex and adrenal cortical hormones, toad poisons and the digitalis saponins. All contain the characteristic perhydrocyclopentanophenanthrene nucleus shown in the chart. The steroids differ from each other by variations in the composition of the side chain (R in the type formula), the degree of saturation of the nucleus, and the number and site of attachment of hydroxyl groups on the nucleus. Of the considerable number of sterols that have been isolated from natural sources, cholesterol is of paramount physiologic significance, since it is the only one which is utilized by higher animals. Due to the presence of an hydroxyl group, cholesterol can exist in the free or esterified form. It is the chief sterol in the animal kingdom, and one of its derivatives, 7-dehydrocholesterol, is recognized as the precursor of a naturally occurring antirachitic vitamin (D$_3$). Ergosterol, which occurs only to a small extent in animal tissues but in considerable amounts in such lower plants as yeasts and fungi, is the provitamin of vitamin D$_2$. A number of additional sterols are rather widely distributed in the plant kingdom, but, like ergosterol, none of these plant products are utilized to any appreciable extent by mammalia.

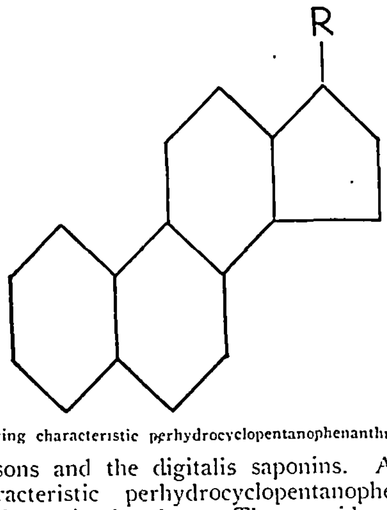

Chart showing characteristic perhydrocyclopentanophenanthrene nucleus.

While these complex lipids are present in only minute amounts in the culinary fats and fat depots, they do make up a major fraction of the lipids of the organs. This is illustrated in the accompanying table.

*Distribution of Lipids in Organ and Depot Fats**

Species	Site	Phospholipids	Cerebrosides	Cholesterol	Triglycerides
Beef	Brain	52	23	19	6
Beef	Liver	70	0	4	25
Beef	Kidney	63	4	1	28
Beef	Intestine	60	3	13	24
Beef	Muscle	27	8	2	62
Beef	Butter	Trace	Trace	Trace	98+
Chicken	Egg yolk	26	2	4	66
Man	Depot	Trace	Trace	Trace	98+
Hog	Depot	Trace	Trace	Trace	98+

* All values are expressed as percentage of total lipids. As will be emphasized later, the content of these complex lipids, particularly the phospholipids, is large in the tissues of greatest physiologic importance.

Consideration of the facilities for fat digestion and absorption shows that ample provision is made for the assimilation of considerable amounts of fat. So far as the stomach is concerned splitting of fat by enzymes (lipases) is at best only of minor importance. Nevertheless the organ assists materially in both digestion and absorption in that it serves as reservoir from which the chemically unaltered fat is discharged at such a rate that the small intestine is not overtaxed. The presence of fat in the meal considerably influences gastric function. Fatty meals leave the stomach much slower than those with large contents of the other organic foodstuffs, and when fat finds its way into the small intestine, it stimulates the production of enterogastrone, a hormone, which, in turn, slows down gastric motility. Of the enzymes having lipolytic action, steapsin, elaborated in the pancreas, is regarded to be the chief one concerned with fat digestion. Its activity is accelerated by soaps and the bile acids. The p_H of the small intestine (close to neutrality) also favors the catalytic action of the enzyme One of the chief properties of the bile is its ability to lower surface tension, which materially speeds up digestion of fat. The small intestine secretes its own particular lipase, and, under certain circumstances, this catalyst can take over the splitting of fat. Data from experiments in which a partial pancreatectomy had been performed indicate that the factor of safety is large, and even in the completely depancreatized dog, maintained with insulin and certain lipotropic products, interference with the digestion of fat is not a problem. Nevertheless, the reports of the extreme diarrheas encountered in some cases of pancreatic insufficiency illustrate the importance of this organ in the utilization of fat.

It is generally accepted that the bile is the most important single secretion concerned in the absorption of fat, and of the biliary constituents, the bile acids are of utmost significance. Data obtained from the steatorrhea associated with obstructive jaundice clearly demonstrate that the abnormality consists not in a failure in the splitting of fat but in the impaired absorption of the fat acids liberated in digestion. These bile acids are believed to combine with the water-insoluble acids liberated by the lipases, to form complexes which are soluble in the intestinal medium and, in this form, pass into the intestinal wall. The pathway for the absorption of fat differs from that of protein and carbohydrate in that the major fraction of the fat enters the body through the lymphatic system. Furthermore, unlike the situation which prevails for the other two major organic foodstuffs, the products liberated by the splitting of fat once having passed into the intestinal mucosa reunite to again form the triglyceride. Phosphorylation is believed to be a factor operating in this resynthesis. This conception was proposed by Sinclair,[4] who observed that, whereas the quantity of phospholipid in the intestinal mucosa was not increased after the ingestion of fat, nevertheless the type of the individual fat acids carried by the phospholipid molecule was primarily dependent on the chemical composition of the dietary fat. He hypothecated the formation of an intermediate phospholipid in the resynthesis. This concept gained strength from more recent work with radioactive phosphorus. Data obtained with this tool[5] indicate that phospholipids are being continuously reformed in the small intestine and that, while this activity continues during inanition, the rate of the reaction is considerably accelerated after the oral administration of fat.

While the concept that the splitting of fat is a requisite for absorption is substantially supported by reliable and clearcut chemical findings,[6] nevertheless evidence has been presented in support of an alternate view. According to Frazer, of England, unsplit fat passes directly into the lacteals, while fat acids, liberated by digestion, pass directly into the portal system and at once to the liver. It is beyond the scope of this article to present the data on which this view is based, and the reader is referred to Frazer's recent review[7] for such information.

In considering the fate of the absorbed fat acids, several pathways are open. They may be incorporated into the more complex lipids, deposited as such in the fat depots, converted into other fat acids, excreted through the gut, be involved in the production of milk fat, transformed into carbohydrate or oxidized to carbon dioxide and water with the liberation of energy.

As has already been mentioned the dietary acids become incorporated into the phospholipids within the intestinal mucosa. Studies with hepatectomized dogs have shown that whereas the phospholipids of the small intestine can originate in these organs themselves, those of the blood plasma owe their existence to the liver.[8] Some years ago Bloor[6] proposed that fat acids were transported in the body in the form of phospholipids, and that of these, lecithin was most important. The evidence for this singular role was not good, but more recent findings[9] indicate that the circulating phospholipids are of the choline-containing (lecithin and sphingomyelin) type.

Further evidence that such phospholipids play a predominating role in fat transport has been supplied by experiments with rats on diets high in fat and low in protein content. Under such circumstances, fat accumulates in large amounts (more than 30 per cent) in the liver. The incorporation of choline or of additional protein in the diet prevents this abnormal infiltration of fat. This so-called lipotropic effect[10] of protein is ascribed to its content of methionine, an amino acid containing a labile methyl group which can be utilized for the synthesis of choline. Both methionine and choline influence lipid metabolism by accelerating the phospholipid turnover in the liver. Investigations with depancreatized dogs, maintained with insulin, have contributed further to the problem. Such animals eventually have fatty livers and, in addition, exhibit a fall in the plasma phospholipids, which, as has been noted, are primarily of the choline-containing type. This can be prevented by the administration of choline or extracts of the pancreas. The effect of the latter cannot be accounted for entirely on the basis of the choline content and, according to Dragstedt,[11] this pancreatic factor, to which he has given the name "lipocaic," is a product of the internal secretion of the pancreas. This has been denied by several groups of investigators, particularly Chaikoff and collaborators, who maintain that the factor is present in the external secretion of that gland.

In addition to phospholipid, it is likely that some transport of fat acids is accomplished through the medium of the cholesterol esters of the blood plasma. As a rule the fat acids, thus combined in the plasma, are the most highly unsaturated ones in that circulating fluid, and it is generally agreed that the esterification occurs in the liver. In this connection it might be well to recall the striking observation that in the depancreatized dog maintained with insulin the decided rise in lipid content of the liver is often accompanied by the complete disappearance of cholesterol esters from the plasma. The administration of pancreatic extracts not only remedies the situation, but even results in a rise in values to somewhat above the normal level.

In considering the fate of fat acids transported in this manner it should be emphasized that the current conception differs extensively from those which were popular less than two decades ago. The discovery of deuterium and other isotopes and the development of methods for their preparation in suitable amounts led to biochemical investigations which practically revolutionized teachings on the fate of physiologic substances.[12] Formerly it was commonly believed that dietary fats were burned soon after absorption had occurred and that, when the caloric requirements of the organism had been met, any excess of fat was conveniently stored in the fat depots. There it remained until the demands for energy were not fulfilled by the diet, whereupon it was mobilized and burnt. Currently it is held that the fat depots are by no means inert materials, but are tissues in a considerable state of flux. Dietary fat acids merge with those of the fat depots, and this mixture is constantly transported to and from the organs. These newer conceptions are based essentially on data secured by Schoenheimer from experiments in which fat acids labeled with deuterium were fed to white mice and rats. In a typical experiment deuteropalmitic acid was fed and the fat acids of the organs and tissues fractionated. Of the labeled product fed a considerable fraction (more than 40 per cent) found its way to the tissues and organs as such, part was degraded to the lower homologues, myristic and lauric acids, another fraction was converted to stearic acid, a higher homologue, and an additional portion to the unsaturated acid, oleic acid. None of the more highly unsaturated ones, linoleic and linolenic, were formed. In this connection mention should be made of the demonstration [13] that fat acids of this type are essential constituents in the diet of the white rat. In their absence retardation of growth becomes evident, renal lesions appear and untimely death occurs. One of the early symptoms exhibited is scales on the feet. Only isolated experiments have been carried out with other species. In one experiment with man in which an adult was maintained for six months on an extremely low fat diet, a definite fall in the linoleic acid content of the circulating lipid was observed. A similar fall has been recorded for the serum lipids of infants with eczemas. Most of such cutaneous disorders were reported as "cured" or "greatly alleviated" when fats containing the more highly unsaturated acids were included in the diet.

[12] Schoenheimer, R.: *The Dynamic State of Body Constituents*, Cambridge, Mass., Harvard University Press, 1942.

The dynamic state of the tissues was demonstrated further by Schoenheimer's observation that fat acids labeled with deuterium eventually disappeared from the body even though the caloric requirements had been met. In mice, the half life cycle of such products ranged from five to eight days. This state of flux is believed to be the physiologic explanation for the formation in the tissues of the type of fat characteristic for a particular species ingesting a diet not particularly high in fat content. When, however, the diet includes considerable amounts of that foodstuff the situation is altered, and now the depot fat begins to closely resemble the dietary fat in chemical composition.[14] This is of considerable economic significance to the swine husbandry industry, which supplies such enormous amounts of culinary fat to the trade. When, for example, certain vegetable foodstuffs, high in a content of fat of low melting point, are incorporated in the diet of hogs the so-called "soft pork" grade, which is more liquid than the usual type of hog depot fat, is deposited. While this product is unquestionably a satisfactory nutrient, the market value is below that of the firmer grades. Owing, however, to the state of flux, it is possible to remedy the situation by merely changing to a diet containing small amounts of the liquid acids and comparatively large amounts of the saturated ones or by supplying a ration in which most of the fat has been replaced by carbohydrate. In the former instance the dietary fat eventually replaces the more liquid type, while in the latter case the excess of carbohydrate is transformed into the acids, and these in turn are deposited.

The physiologic transformation of carbohydrate into fat was first conclusively demonstrated by Lawes and Gilbert [15] in 1877. During the interim, repeated confirmations have been supplied, but the mechanism of the synthesis still remains somewhat obscure. In recent experiments in which the body fluids of mice were enriched with deuterium, the fat acids of the depots were found to contain the isotope. The diet was so low in fat that a synthesis from carbohydrate must undoubtedly have taken place, and the concentration of the isotope and its distribution along the chain was such as to suggest that in this biologic process a condensation of a considerable number of small units had taken place.[12] This hypothesis is further supported by the report [16] that isotopic acetic acid can be utilized for the synthesis of the higher fat acids. In these experiments both the carboxyl-carbon atom and the hydrogen of the methyl group were labeled. The analysis of the fat acids for deuterium resulted in data which could be best explained on the basis of the condensation of many 2 carbon units.

The 2 carbon fragment is also involved in the degradation of fat acids. In 1905 Knoop [17] proposed a mechanism for the oxidation of such acids whereby the long chain was oxidized at the beta carbon atom with the resulting loss of a 2 carbon unit. It was further suggested that the fission progressed successively in such an orderly manner that no matter which fat acid was being catabolized eventually 1 mole of butyric acid was formed. This was subsequently oxidized at the beta carbon atom with the production of the ketone bodies. Knoop's contention received support from the work of Dakin,[17a] who demonstrated that beta oxidation could occur in vitro and isolated some of the intermediates of the reaction. The idea was further substantiated by Embden's observation [18] that the perfusion of fat acids through the liver resulted in the liberation of acetone. In addition it is common knowledge that ketone bodies are formed during the catabolism of fat by man. In the healthy person the urinary excretion of such ketones is increased by the excessive oxidation of fat as it occurs on a high fat diet or as in fasting. For the same reason ketonemia and ketonuria are common occurrences in uncontrolled diabetes mellitus. While this classical theory, whereby oxidation occurs at the beta carbon atom, has stood the test of time, the corollary, that the oxidation of 1 mole of any particular fat acid gives rise to only 1 mole of the ketone body, is currently not accepted. Stadie [19] has recently reviewed the literature on this phase of the problem. Two alternate proposals have been made. One of these,

first suggested by Hurtley[20] in 1916 and revived by Jowett and Quastel[21] in 1935, postulates that the chain is oxidized simultaneously along its whole length at alternate carbon atoms beginning at the beta position. As a result the whole molecule is converted into ketones which break up to form 4-carbon chains. Accordingly, beta-oxybutyric acid is again formed, but under these circumstances butyric acid would yield 1 mole; octanoic, 2; lauric, 3, and palmitic, 4 moles of the ketone bodies. Previously it was assumed that only 1 mole would arise from all of the acids. While this newer suggestion is compatible with a considerable amount of data accumulated from experiments with liver slices as well as with healthy intact animals, divergent reports are also available. Thus the 5 carbon chain of valeric acid gives rise not only to glucose but also to acetone, suggesting the condensation of two 3 carbon chains to form the sugar, and of two 2 carbon fragments to give rise to the ketone. Other acids containing an odd number of carbon atoms have been shown to be both glucogenic and ketogenic. In addition Deuel and co-workers observed a greater increase in the ketone excretion following the oral administration of hexanoic acid to the intact white rat than when butyric acid was given. These and other observations led MacKay[22] to propose that oxidation of fat acids proceeded at the beta-carbon atom, as suggested by Knoop, but that the 2 carbon fragment, liberated in this manner, recombined to form the ketone bodies. The report that acetic acid, administered per os to rats, is converted to aceto-acetic acid is in good accord with this conception. Furthermore, when octanoic acid, containing the C^{14} isotope in the carboxyl group, was equilibrated with liver slices the distribution of the tag in the isolated aceto-acetic acid was in close agreement with values predicted on the basis of this beta-oxidation-condensation theory. Schoenheimer's[17] observation that deuteropalmitic acid gives rise to deuteromyristic acid is further proof for the removal of the 2 carbon fragment. On the other hand, Stadie[19] pointed out that some experiments with beta-hydroxybutyric acid led to data more in accordance with values to be expected on the basis of multiple alternate oxidation as proposed by Hurtley.[20] Evidently both mechanisms can operate, and, at present, it seems advisable to defer judgment concerning the predominance of either path.

According to Verkade[23] still another path is open for the catabolism of fat acids. In this scheme the terminal methyl group is first oxidized with the formation of a dicarboxylic acid, which is in turn successively oxidized at the two positions beta to the carboxyl groups. While there is some experimental justification for this proposal, it is generally believed that, even though this so-called *omega-oxidation may* operate, the amounts of acids thus catabolized are so minimal that in the end this route is of little physiologic importance.

It is generally agreed that the complete oxidation of fat acids to carbon dioxide and water takes place in two stages. The initial one, which occurs almost exclusively in the liver, results in the formation of the ketone bodies, already referred to. It has been reported[24] that the presence of adenosine-triphosphate, or a system giving rise to it, is necessary for this first phase. The second one, which takes place almost entirely in the extrahepatic tissues, particularly the kidneys and muscles, consists of the disposal of the 4 carbon chain with the production of water and carbon dioxide. It has been suggested that certain intermediates, which also have been found to operate in the final disposal of carbohydrate, are involved in the ultimate breakdown of fat. Direct evidence for this idea has been supplied by Buchanan and others,[25] who incubated tagged acetate and aceto-acetate with kidney homogenates and detected the isotope (C^{13}) in the alpha-keto-glutaric, fumaric and succinic acids isolated from the reactions mixture. All three had previously been shown to be members of the tricarboxylic acid cycle involved in carbohydrate catabolism.

While it is probable that the 2 and 4 carbon metabolites can be disposed in the manner described, sight should not be lost of other paths for the utilization of the acetate fragment. Thus the conversion of this short chain to the higher fat acids has been demonstrated, the synthesis of cholesterol from acetate accepted, and the utilization of the acetyl group for the detoxication of certain amines established. Acetate and aceto-acetate have also been assigned the role of intermediates by some investigators in their proposed scheme for the conversion of fat to carbohydrate. This issue continues to be exceedingly controversial, and, while some of the more recent findings favor the interconversion, an evaluation of the evidence available generally leads to the verdict that the case has not been proved.

Fat acids need not follow any of the pathways outlined. This is illustrated in studies on the origin of milk fat. Currently it is held that the major portion of such fat arises directly from the triglyceride fraction of the blood lipids and that the chemical composition of it is, in turn, governed to a considerable extent by the dietary habits of the host. Hilditch,[26] of England, has clearly established that the chemical nature of the milk fat of the dairy cow can be significantly altered by dietary management. However, this comparatively simple explanation does not account for all the facts observed in this phenomenon. Butter obtained from the dairy cow, for example, contains unusually large amounts (8 to 10 per cent) of fat acids containing 4 to 10 carbon atoms. Similar observations are recorded for the milk fat of other ruminants, but the distribution of the individual constituents within this fraction varies significantly with the species. In contrast, the milk of the pig, the dog and the human being contains almost negligible amounts of these acids of low molecular weight, resembling in this respect almost all other natural fats. These inconsistencies cannot be ascribed to differences in dietary habits. Man is notable for his continued ingestion of cow's milk even after maturity has been attained. This does not occur in the dairy cow. If these particular acids are dietary in origin, the milk fat of the lactating woman should of necessity contain more and not less of such acids of low molecular weight. It has been suggested that the source of these fatty acids in the milk of ruminants may be from the fermentation which takes place in the stomach. In this connection it should be recalled that such acids are not deposited in significant amounts in the tissues of the rat even though they may be supplied in abundant amounts in the diet. These observations and others have led to a belief that fat acids of low molecular weight are actually synthesized in the mammary gland and that the variations in the distribution of them in the milks of different species are to be ascribed to metabolic differences in their respective glands.

[26] Hilditch, T. P.: The Chemical Composition of Natural Fats, New York, John Wiley & Sons, Inc., 1940.

Cowgill[2] in his review devoted considerable space to the controversy on the relative nutritive value of butter fat and the margarines. He referred to the work by Schantz, Elvehjem, and Hart, of Wisconsin, who compared the nutritive value of mineralized milk rations, supplemented separately with a variety of vegetable fats and butter, and concluded that during their early life young rats receiving the ration containing the butter fat showed the best response in growth. In additional experiments these workers obtained data which led them to believe that butter fat is superior to the margarines so far as growth of young rats is concerned. The same group[27] recently determined the vaccenic acid (an isomer of oleic acid) content of a variety of fats and oils and reported that, whereas the acid is present in small amounts (less than 0.85 per cent) in butter fat, lard and beef fat, none was detected in the number of vegetable fats examined. This study followed a report[28] that the growth of rats on a ration containing rape seed oil as the source of fat was inferior to the rate observed when butter alone was employed as the dietary fat. The inclusion of 0.1 per cent of vaccenic acid in the rape seed oil diet resulted in a growth rate which practically duplicated the one recorded for the ration containing butter. It was suggested that superiority of butter fat over the margarines was due to the presence of vaccenic acid.

According to Cowgill, Deuel and collaborators were unable to demonstrate this superiority of butter. In a comprehensive investigation of the problem, this latter group observed satisfactory growth and reproduction of ten generations of rats during which time the butter fat of a ration, known to be satisfactory for growth and reproduction, was replaced by a margarine. Other investigators agreed with Deuel. In this connection the latter has remarked on the observation by Hilditch that human milk fat more closely resembles the margarines in chemical composition than does the fat obtained from the milk of the dairy cow. It should be pointed out that experiments have not been conducted with human subjects and that differences observed in the rat may not apply to man. In commenting on this problem Cowgill pointed to the differences in the rations employed, the strains fed and the conditions under which the investigations were carried out by the several groups, and suggested that the matter might be clarified by providing uniform conditions in future studies.

Turning now to the problem of the utilization of the complex lipids, it is evident that our knowledge of the digestion and absorption of these is scanty. With regard to the phospholipids, most of the data are limited to the lecithins. These are believed to be split by enzymes in the duodenum. At least this is the conclusion reached from data obtained on the composition of the thoracic lymph collected before and after the feeding of these particular phospholipids. To date it has not been established whether lecithins can enter the portal blood stream directly in the unsplit form. Studies on the utilization of cephalin and phosphotidyl serine have not been recorded, and those pertaining to sphingomyelin are fragmentary. With regard to the cerebrosides, the data available in the literature are few and conflicting. It is clear that this phase of lipid metabolism needs investigation. From some unpublished work obtained in this laboratory it is apparent that the lipid fraction of the brain, which contains considerable portions of all of these complex lipids, is reasonably well utilized, but not as well as the triglycerides. These studies have, however, not been carried beyond the preliminary stages.

In contrast to the lack of information referred to, the literature contains numerous investigations on the utilization of cholesterol and its esters. Much credit should be given to Gardner, of England, who initiated so many significant studies on the origin and fate of this sterol. As a consequence of the analysis of thoracic lymph, following the feeding of cholesterol and its esters, it has been established that regardless of whether fed in the free or esterified form, increases in both fractions occur in the lymph. This indicates that during absorption both esterification and hydrolysis occur in the small intestine. As a rule the absorption of cholesterol takes place best in the presence of dietary fat. This may be due to supplying fat acids for esterification. As in the case for fat, the absorption of cholesterol is accelerated by the presence of bile, and it is believed that this is accomplished by a combination of the alcohol with bile salts with the formation of soluble complexes.

It is agreed that all these complex lipids can be synthesized by higher animals from comparatively simple products. This is illustrated by experiments with rats on diets practically devoid of such lipids. In such circumstances, growth occurred with a corresponding rise in the content of these lipids in the tissues. Similarly it is evident that such lipids increase in amount in the suckling infant even though the milk contains insufficient amounts to account for the increment. According to Block and Rittenberg,[29] acetic acid, when fed to mice and rats, leads to the synthesis of cholesterol. The deuterium in the dietary acetate was present in both the nucleus and the side chain of the steroid.

Mention has already been made of the role of the phospholipids in fat absorption and transport. In addition they undoubtedly are intimately associated with other physiologic activity, inasmuch as the more active tissues contain the larger amounts of such lipids. Heart muscle, for example, contains practically twice as much as skeletal muscle. These lipids are intimately associated with protein, and it is believed that the lipids of blood plasma are combined with protein. The prosthetic group in the thromboplastic protein of plasma and tissues, so intimately associated with the clotting of blood, is considered to be a complex lipid of the phospholipid type. The role of cholesterol in the living organism is undoubtedly a manifold one. Its presence in practically all tissues indicates this. However, it is not possible to describe all of its various functions. Mention has

already been made of its relationship to the natural form of vitamin D. In addition it can give rise to the bile acids and some of the sex hormones. Analyses of normal tissues have proved the presence of a variety of degradation products of cholesterol which conceivably can be considered to be the precursors of additional hormones.

The distribution of these complex lipids in the blood, during the postabsorptive state, and in the organs does not vary materially over considerable lengths of time in the healthy subject. As a rule the lipid levels in the corpuscles remain unaltered during disease, but definite fluctuations from the normal values are encountered in the plasma. The fall in cholesterol esters, observed in diseases of the liver, is ascribed to a failure in formation in that organ. Falls in total cholesterol values have been observed in certain infections, while hypercholesterolemia often accompanies nephrosis. The levels of plasma cholesterol vary appreciably with thyroid activity, being subnormal in hyperthyroidism and elevated above normal in hypothyroidism. The reader is referred to Bloor's monograph[30] for references to and a more detailed discussion of the variations in the levels of the plasma lipids under pathologic conditions. The role of the lipids in atherosclerosis has recently been reviewed.[31]

Variations from the normal lipid content are encountered in the organs of a number of pathologic conditions grouped as the "lipidoses." One of these, the xanthomatoses, is characterized by a deposition of cholesterol in large quantities in the tissues. In the xanthomatosis of the bones and organs and in the Schuller-Christian syndrome the plasma cholesterol levels are not elevated, whereas a definite hypercholesterolemia is commonly observed in xanthoma tuberosum. In the latter condition the treatment of the disease by prescribing a cholesterol-low or plant diet has been reported as successful. On the other hand, some patients do not respond in this manner to the change in diet. In Niemann-Pick disease the disorder is in the accumulation of sphingomyelin, while in infantile amaurotic familial idiocy (Tay-Sachs disease) the gangliosides increase extensively. Gaucher's disease is characterized by the deposition of large amounts of the cerebrosides, particularly in the spleen. In contrast to galactose, as is the case for the cerebrosides of the healthy subject, glucose was found to be the carbohydrate constituent of the lipid. With the exception of some of the xanthomatoses the levels of the individual lipids in the plasma in these pathologic conditions fall within the normal range, and no satisfactory explanation has been made for these unusual situations. A detailed description of these anomalies and speculations concerning their origin are available in a recent review.[32]

SUMMARY

1. The incorporation of suitable amounts of fat (triglycerides) in the diet increases the "staying power" of the ration and the substitution of fat for carbohydrate decreases fermentation in the gut.

2. Triglycerides of plant and animal fats are equally well digested and absorbed provided that liquefaction of these occurs in the small intestine. Plant sterols are not absorbed to any significant extent by man, while cholesterol, the chief sterol of higher animals, is well utilized.

3. Depot fats consist primarily of triglycerides. In contrast, cholesterol, the phospholipids and the cerebrosides occur in predominating amounts in the actively functioning organs of animals.

4. Pancreatic lipase and the bile salts are the chief factors in the digestion and absorption of triglycerides from the intestine.

5. Cholin-containing phospholipids are intimately associated with the transport of fat acids in the body. These acids may be incorporated in the complex lipids, deposited in the fat depots, converted to other fat acids, excreted into the gut, utilized in the formation of milk fat or oxidized to carbon dioxide and water with the liberation of energy.

6. While the majority of the fat acids can be synthesized by the animal organism, linoleic and linolenic are apparently exogenous in origin. Either one of the latter two is an essential constituent in the diet of the white rat, and may be required by man.

7. Degradation of fat acids takes place in two stages. The first phase, occurring almost exclusively in the liver, consists in the production of the ketone bodies, which are disposed of in the final stage in the extrahepatic tissue (notably in the kidneys and muscles).

8. With the exception of those of low molecular weight (C_4 to C_{10} inclusive) the fat acids of milk fat originate from the triglycerides of the blood. The composition of milk fat can be altered by dietary management. The controversy on the comparative nutritive value of butter and the margarines still exists.

9. Cholesterol, the phospholipids and the cerebrosides can be synthesized by the animal organism. Increased deposition of these occurs in the actively functioning organs in the different types of lipidoses.

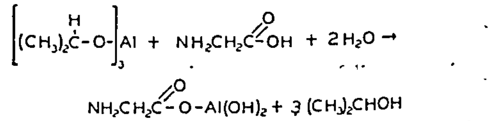
AUSTIN SMITH, M.D., *Secretary.*

DIHYDROXY ALUMINUM AMINOACETATE.—Alglyn-Brayten.—A basic aluminum salt of glycine containing small amounts of aluminum hydroxide and glycine.—$C_2H_6O_4NAl$.—M. W. 135.05.—The structural formula for basic aluminum aminoacetate may be represented as follows:

$$NH_2CH_2C(=O)-O-Al(OH)_2$$

Dihydroxy aluminum aminoacetate is prepared by the reaction of aluminum isopropoxide with glycine according to the following reaction:



$$\left[(CH_3)_2\overset{H}{C}-O-\right]_3Al + NH_2CH_2C(=O)OH + 2H_2O \rightarrow NH_2CH_2C(=O)-O-Al(OH)_2 + 3\,(CH_3)_2CHOH$$

The precipitated dihydroxy aluminum aminoacetate is filtered with suction, washed with isopropyl alcohol and dried at a temperature not exceeding 71 C. The aluminum isopropoxide is prepared by the reaction of aluminum in shreds or strips with anhydrous isopropyl alcohol, catalyzed by 0.03 per cent mercuric chloride, followed by distillation under vacuum.

[30] Bloor, W. R.: Biochemistry of the Fatty Acids and Their Compounds, the Lipids, New York, Reinhold Publishing Corporation, 1943.

[31] Hirsh, E. F., and Weinhouse, S.: The Role of Lipids in Atherosclerosis, Physiol. Rev. **23**: 185 (July) 1943.

[32] Thannhauser, S. J., and Schmidt, G.: Lipids and Lipidoses, Physiol. Rev. **26**: 275 (April) 1946.

Actions and Uses.—Dihydroxy aluminum aminoacetate acts as a gastric antacid when taken orally and is thus useful for the control of hyperacidity in the management of peptic ulcer. It shares the properties of the aluminum hydroxide gel preparations, over which it has no important advantages. Its buffer action is not significantly more prompt, great or prolonged than that of the liquid preparations of aluminum hydroxide gel when compared on the basis of equivalent aluminum content. Compared with dried aluminum hydroxide gel (U.S.P.) it possesses only slightly more prompt buffering action and shares with that preparation the convenience of tablet form in which it is used. Because it contains from 50 to 60 per cent less aluminum than the aluminum hydroxide preparations, the formation of astringent aluminum chloride in the intestine is theoretically reduced, which is claimed to result in less constipating action. The clinical significance of its slightly more prompt buffering action than dried aluminum hydroxide gel or its tendency to produce less constipation than aluminum hydroxide preparations in general is open to question. Claims that dihydroxy aluminum aminoacetate is generally superior to aluminium hydroxide preparations are disallowed until more clinical evidence is available to demonstrate significant differences. The claimed prompt disintegration in the stomach of dihydroxy aluminum aminoacetate tablets when swallowed whole appears to offer only limited advantage for the ambulant treatment of persons unable to chew tablet preparations of dried aluminum hydroxide gel, since the latter may be readily broken up prior to administration when that becomes necessary.

Dosage.—Dihydroxy aluminum aminoacetate is administered orally in tablet form. One to two 0.5 Gm. tablets after meals and at bedtime or as otherwise required to control hyperacidity are recommended. As with other internally administered aluminum compounds, constipation may occur from prolonged administration.

Tests and Standards

Dihydroxy aluminum aminoacetate is a white, odorless powder with a faint sweet taste. It is insoluble in water and organic solvents, but soluble in dilute mineral acids and solutions of fixed alkalies to yield a cloudy solution which clarifies on heating.

Dry 2 Gm. of dihydroxy aluminum aminoacetate, accurately weighed, to constant weight at 130 C. This requires two to three day's drying. The loss in weight does not exceed 14.5 per cent.

Prepare a suspension of 1 Gm. of finely ground dihydroxy aluminum aminoacetate in a glass-stoppered flask containing 25 cc. of distilled water. Mix the contents for 5 minutes, and then let stand for 5 minutes. The pH should be 6.5 to 7.5.

Transfer 0.2 Gm. of finely ground dihydroxy aluminum aminoacetate, accurately weighed, to a glass-stoppered flask containing 25 cc. of tenth-normal hydrochloric acid. Agitate the mixture vigorously for 5 minutes, and then let it stand for 5 minutes. The pH must be above 3.0.

To 20 cc. of an aqueous suspension (1 in 25) of dihydroxy aluminum aminoacetate add hydrochloric acid dropwise until the compound just dissolves to form a clear solution. Divide the solution into two equal portions. To one portion add an excess of ammonia T.S.; a white flocculent precipitate of aluminum hydroxide is formed which is insoluble in an excess of ammonia but soluble in sodium hydroxide T.S. To the other portion add one drop of liquified phenol and 5 cc. of sodium hypochlorite T.S.; a blue color is produced, characteristic of aminoacetic acid.

Dihydroxy aluminum aminoacetate shows no heavy metals when subjected to the test outlined in U.S.P. XIII, page 657.. Dihydroxy aluminum aminoacetate shall be free of mercury when a solution containing 1 Gm. of the compound dissolved in 10 cc. diluted hydrochloric acid is shaken with 10 cc. of a solution of dithizone in carbon tetrachloride (concentration 2 mg. per 100 cc.): The CCl_4 layer does not turn orange (Feigl, F.: Qualitative Analysis by Spot Tests, ed. 3, New York, Elsevier Pub. Co., 1946, p. 49).

Suspend 5 Gm. of dihydroxy aluminum aminoacetate in 100 cc. of tenth-normal potassium permanganate acidified with 10 cc. of concentrated sulfuric acid. Reflux the mixture for 30 minutes and distil a 10 cc. sample. The distillate must be free from acetone as shown by the nitroprusside test (*N.F.* VIII, p. 20).

Add 0.25 Gm. finely ground dihydroxy aluminum aminoacetate to 50 cc. tenth-normal hydrochloric acid. Allow to stand 10 minutes with occasional agitation. At the end of 10 minutes back titrate the excess acid with tenth-normal sodium hydroxide to a pH of 3.8 using bromphenol blue T.S. as indicator. One gram of dihydroxy aluminum aminoacetate neutralizes at room temperature not less than 125 cc. and not more than 175 cc. of tenth-normal hydrochloric acid under these conditions.

Transfer about 1 Gm. of dried dihydroxy aluminum *aminoacetate, accurately weighed, to a platinum dish.* Add 5 cc. nitric acid and 2 cc. of sulfuric acid (1:1). Fume off the acids and ignite in a muffle furnace at 1,200 to 1,500 C. Dissolve the residue in 10 cc. of hydrochloric acid and 5 cc. of sulfuric acid (1:1) and transfer to a 600 cc. beaker. Dilute with water to 400 cc. and add strong ammonia solution until the solution is just basic to methyl red. Heat to boiling, filter and wash the precipitate with hot water until the washings are free from chloride. Dry the precipitate, ignite it at 1,200 - 1,500 C. to constant weight, cool and weigh the Al_2O_3 so obtained. The calculated aluminum oxide content of dry dihydroxy aluminum aminoacetate is not less than 34.9 per cent and not greater than 38.7 per cent.

Determine the nitrogen content by the semi-micro Kjeldahl method (U.S.P. XIII, p. 673), using 0.1 Gm. of dried dihydroxy aluminum aminoacetate, accurately weighed. The per cent of nitrogen present in dry dihydroxy aluminum aminoacetate is not less than 9.8 or greater than 10.8 per cent.

EDITORIAL ANNOUNCEMENT

The compositors returned to work on Monday, June 28. This issue of The Journal has been prepared in part by the use of Vari-Typer machines.

EXPERIMENTAL NECROTIZING ARTERITIS

Summarizing several years of experimental work, Holman[1] and his associates of the Department of Pathology, University of North Carolina, concluded that degenerative lesions affecting principally the aorta, pulmonary artery, auricular endocardium and coronary arteries may be produced with regularity in young dogs by controlling two factors: (*a*) diet and (*b*) renal efficiency. Both factors are necessary, either one in itself being ineffective.

Two diets were used in these experiments. The first or "standard diet" consisted of 32 parts of calves' liver, 25 parts of cane sugar, 25 parts of corn starch, 12 parts of butter and 6 parts of commercial cod liver oil plus enough tomato juice to make a paste. Each gram of this diet contained 3 calories. The diet was fed in amounts to furnish 75 calories per kilogram per dog daily. Five grams of kaolin and 1 mg. of salt mixture were added to each daily feeding. The second or "kennel diet" consisted of selected table scraps reinforced by the addition of 6 per cent commercial cod liver oil.

After feeding of one of these diets for eight to twelve weeks renal injury was produced by one of several methods,. usually by a minimum lethal dose of uranyl nitrate injected subcutaneously or by mercury chloride injected intravenously. Bilateral nephrectomy was used in a few cases. The animals died of uremia or were killed seven to thirty-five days after the renal injury.

In 87 per cent of the 55 dogs thus far tested arterial lesions were found. These varied from (±) equivocal lesions discovered only in microscopic sections to (+++) gross necrotizing lesions 1 cm. in maximum diameter. The first detectable anatomic change is edema, swelling, fragmentation and necrosis of collagen. The subsequent fibrin and leukocytic reactions were presumably secondary responses.

Evidently there are one or more anticollagens in the selected diets which are neutralized or eliminated by normal renal function. Substitution of corn oil for cod liver oil in either diet renders the diet nontoxic. That the toxic factor is not unique to cod liver oil, however, is deduced from the fact that similar necrotizing arteritis is occasionally noted in nephrectomized dogs in which beef fat is substituted for cod liver oil. The evidence thus suggests that the toxic factor responsible for the necrotizing arterial lesion is a lipid.

If so, the question naturally arise as to the possible effect of vitamin E, a "fat antioxidant" on the production of the arterial lesions.[2] To test this, a capsule containing 20 mg. of mixed natural tocopherols was given daily by mouth, from two days before to two days after the renal injury The dogs thus treated survived for eight to thirty days after the renal injury. At necropsy arterial lesions were not noted. The conclusion is drawn that oral administration of adequate doses of vitamin E is a preventive of experimental necrotizing arteritis in dogs, due to a combination of toxic lipids and reduced renal function.

Acute necrotizing arteritis in dogs has a close human counterpart in periarteritis nodosa and rheumatic arteritis in man

RADIOACTIVE LOCALIZATION OF BRAIN TUMORS

In 1947 Moore of the Department of Surgery, University of Minnesota, found that fluorescein injected intravenously into patients has the property of elective localization in malignant tissues.

Five cubic centimeters of a 20 per cent sodium fluorescein solution was injected intravenously from three to eight hours before a planned laparotomy for gastric carcinoma At the operation the suspected lesions were inspected with an ultraviolet lamp. Differences between normal and malignant tissues were then noted, the malignant tissues fluorescing with a vivid yellow color. The main exceptions were in cases in which the malignant tissues were situated more than a few millimeters below the surface. In these cases, little or no fluorescence was noted, presumably because ultraviolet light can penetrate only a few millimeters through surrounding tissues. In 11 of 17 cases of of malignant tumors of the gastrointestinal tract a high grade fluorescence was associated with verified diagnoses of malignancy by microscopic methods. Three cases showed only slight fluorescence. In an additional 3 cases malignant tumors or tumor fragments failed to fluoresce, the majority of the partial or complete failures occurring in bulky tumors. Necrotic tissues did not fluoresce. Edema and cyst formation at times accounted for erroneous tests.

More reliable results were obtained with brain tumors. Twelve patients suspected of having intracranial neoplasms were examined. Tissues were obtained from suspected areas by aspiration needle. Exaggerated fluorescence was observed under ultraviolet light. There was a perfect correlation between results by this technic and subsequent diagnosis by standard pathologic methods.

[2] Holman, R. L.: Proc. Soc. Exper. Biol. and Med. 66:307 (Nov.) 1947.

[1] Moore, G. E.: Science, **106**:130, 1947.

In an attempt to extend the clinical usefulness of this technic,[2] a radioactive derivative of fluorescein (sodium diiodofluorescein) was synthesized with I^{131}. The amount of I^{131} added was adjusted to give 1 millicurie of radioactivity per 10 cc. of a 2 per cent solution of the fluorescent dye. An amount of dye calculated to give 500-600 microcuries of radioactivity was injected intravenously into 12 patients with suspected brain tumors. From two to four hours later radioactive tests were made with a specially screened Geiger-Müller tube. Background radiation was eliminated by a 2 cm.-thick lead shield provided with a lead cone to reduce the area exposed. Thin lead foil was placed over the counter window to filter out beta radiation. Counts were taken for three to five minute intervals at each of several positions on the skull with the cone of the detection unit directly on the skin. A majority of the tests were carried out without knowledge of the neurologic findings, roentgen examination or staff opinion. A definite area was outlined on the skull over the apparent site of the radioactive tissues.

In all cases this outline coincided closely with the extent of the superficially situated meningeoma subsequently found at operation. Correct positive and negative findings were noted. In 3 cases the preoperative clinical diagnosis was proved wrong. In one negative radioactive test no tumor but an aneurysm of the right internal carotid was found on operation. In a second case the preoperative diagnosis of subdura hematoma was changed to that of tumor by the radioactive test. The radioactive diagnosis was in all cases confirmed by the subsequent operation.

Preliminary experiments utilizing induced brain tumors in mice have revealed a concentration of the radioactive dye in tumor tissues as high as eighty times that found in the adjacent normal tissues. A possible therapeutic use of the radioactive dye has not yet been considered.

Current Comment

METABOLIC FATE OF THYROXIN

The development of highly sensitive technics for the estimation of radioactive isotopes has made possible the study of the metabolic fate of active drugs such as thyroxin. When this hormone, labeled with radioactive iodine, is injected into rats, more than 50 per cent of the administered dose may be recovered after two hours in the gastrointestinal tract, liver and pancreas, mainly in unaltered form.[1] Two days after the injection, about 80 per cent may be recovered from the feces, largely unchanged, while some 11 per cent is present as inorganic iodide in the urine. The liver, kidneys, adrenals, ovaries and lymphatic organs tend to maintain their radioactivity at this time. The thyroxin appears to enter the intestinal tract by way of the liver, the organ active in the excretion of certain other halogenated compounds. The results are interesting especially because they form a possible experimental basis for any relationships which may exist between thyroid and hepatic function. They were obtained with relatively large doses of thyroxin (about a milligram); preliminary work with physiologic amounts indicates a similar trend with respect to distribution.

REFLECTIONS ON GENIUS

W. R. Brain,[1] in a review of current thinking on the mental factors which tend toward genius, considers intelligence the most important and the one distinguishing feature in families in which great ability is transmitted through successive generations. The definition of genius as proposed by Kretschmer is quoted:

> We shall give the name genius to those men who are able to arouse permanently, and in the highest degree, that positive, scientifically grounded feeling of worth and value in a wide group of human beings. But we shall only do so in those cases where the value arises with psychological necessity, out of the special mental structure of the bringer of value, not where a stroke of luck or some coincidence of factors has thrown it in his lap.

Another factor of importance is the physiologic organization of nerve cells into functional patterns called "schemas." The genius presumably excels the ordinary person in that he is richer in the numbers and patterns of his physiologic "schemes." The relationship between intelligence and the use of words is important, as high levels of conceptual thought are possible only with a highly developed capacity for verbal symbolization. Dr. Johnson, Coleridge and Shelley are examples of association of prodigious memory with genius. Most remarkable feature of the creations of genius is considered to be the extent to which thought arises apparently independently of the conscious mind, usually accompanied by a high degree of emotional excitement. The person so affected is often endowed with a continuous unrelenting energy for work until the task is fulfilled. Poincaré illustrates inspiration in discussing a mathematical discovery:

> One is at once struck by these appearances of sudden illumination, obvious indications of a long course of previous unconscious work.... This unconscious work...is not possible, or in any case not fruitful, unless it is first preceded and then followed by a period of conscious work. These sudden inspirations are never produced...except after some days of voluntary efforts which appeared absolutely fruitless, in which one thought one had accomplished nothing, and seemed to be on a totally

[1] Brain, W.R.: *Some Reflections on Genius*, Lancet 1: 661-665 (May 1) 1948.

wrong track. These efforts, however, were not as barren as one thought; they set the unconscious machine in motion, and without them it would not have worked at all, and would not have produced anything. The necessity for the second period of conscious work can be even more readily understood. It is necessary to work out the result of inspiration, to deduce the immediate consequences and put them in order, and to set out the demonstrations, but, above all, it is necessary to verify them.

Goethe states that "No productiveness of the highest kind, no remarkable discovery, no great thought that bears fruit and has results is in the power of any one; such things are above earthly control." Poetic genius, administrative genius, musical genius and genius in its relation to mental disorder are discussed. The creative genius, whether he be artist, scientist or abstract thinker, is in all cases considered to be inspired in the same way, differing only in that his unconscious and conscious application is directed to other subject matter. Discussing mental disorder and neuroticism as compared to the quality of genius, the author concludes that the nervous traits in the genius are genetically and psychogenetically identical with those which we term neurotic in the ordinary man.

ICTERUS OF THE NEWBORN

Apparently the largest potential source of iron for new blood formation in the infant[1] is the destruction of erythrocytes in the early days after birth. The concentration of serum bilirubin, which is approximately 1 mg. per hundred cubic centimeters at birth, commonly rises by the fifth day to about 5 mg., a level at which jaundice is usually apparent in most infants. This rise has been attributed[2] to the hemolytic action of an increased level of blood lipid brought about by a sudden increase in dietary fat after birth (the placenta is impermeable to fat). High fat diets induce accelerated destruction of red blood cells and production of biliary pigment, demonstrated in experimental animals.[3] When the child's formula is limited to 0.03 per cent fat in place of the usual 3.6 per cent, the rise in serum bilirubin is much less. Thus a considerable part of the hyperbilirubinemia in the newborn can be controlled by a reduction in the proportion of calories obtained from the dietary fat.

STATISTICAL STUDIES OF HEART DISEASES

Moriyama and Gover[1] note that the most important infectious diseases have given way to the chronic degenerative diseases as the chief causes of mortality. Thus the death rate for tuberculosis in 1945 was only 21 per cent of the rate in 1900, and the average pneumonia rate of 49 per 100,000 population in the five year period 1941 to 1945 contrasts markedly with the average of 161 per 100,000 population in the years 1900 to 1904. During this period of extraordinary advances in the public health the death rate for heart diseases climbed steadily. In the forty-five years since 1900, the death rate for heart disease increased from 137 to 322 per 100,000 population, while the death rate for all causes dropped from 1,719 to 1,062 per 100,000 population in the United States death registration states. These trends of mortality have been described in terms of crude and annual death rates. The aging of the population in the United States is an important factor in the upward trend of the death rate for heart disease. This tendency has been reinforced by the decline in the birth rate and the curtailment of immigration. During the period from 1900 to 1940, the median age of the population of the United States increased from 22.9 to 29.0 years. The age distribution of total deaths has changed in a pronounced manner, reflecting in part the change that has taken place in the age distribution of the living population. In 1880, 40 per cent of the recorded deaths were of persons under 5 years of age, while 14 per cent were 65 years of age and over; in 1940 only 10 per cent of deaths were of persons under 5 years of age, while 46 per cent were 65 years of age or older. Practically half the deaths occurring at the present time are among persons in the definitely older age brackets. The effect of these changes in the age composition of the population on the death rates can be eliminated by computing age-adjusted death rates. The tendency for the chronic and degenerative diseases of middle and old age to replace the infectious diseases as leading causes of death is not essentially altered when the changing age distribution is taken into account. Heart disease has progressed in the forty year interval from third to first place, nephritis from seventh to fourth, cancer from eighth to second and diabetes from eighteenth to eighth place, while tuberculosis, pneumonia, diarrhea and enteritis, diphtheria and other communicable diseases have declined from higher to lower ranks. Since the upward trend is evident even in age-adjusted rates for some of the diseases characteristic of middle and old age, the aging of the population could not be wholly responsible. The decline in the mortality rates for infectious diseases including tuberculosis and pneumonia has been so rapid that, despite the increase in mortality for the old age diseases taken as a group, there has been a downward trend in the crude death rate for all causes involved. The authors estimate, on the basis of a crude general death rate of about 14 per 1,000 population in 1980, that deaths from heart disease will constitute roughly 32 per cent of all deaths occurring in that year. Trends of mortality from syphilis, from acute rheumatic fever, and other infections which may lead to specific heart conditions, are definitely downward. With respect to the larger group of degenerative heart diseases, much can be done at present to postpone the onset of cases and to slow their progress. Heart disease, the authors believe, will probably continue to play the principal role in the upward trend of mortality unless some revolutionary advance is made bearing on the prevention and treatment of cardiac diseases.

ORGANIZATION SECTION

Association News

RED CROSS BLOOD PROGRAM

The American Red Cross has sent to the American Medical Association its interpretation of its action of the House of Delegates June 23, 1948 regarding American Red Cross Blood Program. The statement which follows has been referred to the special committee established to confer with the American Red Cross on this subject:

The House of Delegates approved the recommendation of its reference committee that there be no change in the "approval in principle" of the National Blood Program of the American Red Cross. The referencce committee expressed its opinion as to how "approval in principle" be construed. The American Red Cross is in substantial agreement with that opinion and with reference thereto makes the following specific observations.

It was the opinion of the reference committee that "local control must be by the county medical society." This is in accordance with existing Red Cross policy. In fact, the Red Cross has gone beyond this and has laid special emphasis on the methods whereby the local medical society may secure complete control of the technical program.

The reference committee also thought that "the local medical society should be the contact in the initial contemplation of inauguration of a new blood bank." This is likewise in accordance with Red Cross policy which clearly states that the local medical societies, hospital organizations and public health authorities must be in complete accord with the establishment of a blood center before any action is taken. The Red Cross has, in fact, gone beyond this by making certain that the medical societies in surrounding counties are consulted and are in complete accord before any attempt is made to establish a regional center.

The House of Delegates approved the recommendation of its referencce committee that the American Medical Association committee which has been considering blood banks "be enlarged to nine members with definite instructions to meet at stated intervals at the call of either the chairman of its committee or that of the Red Cross." The Red Cross has worked with this American Medical Association committee with results satisfactory to both organizations. It stands ready to join with the American Medical Association in even greater effort and cooperation to attain objectives satisfactory to each.

The reference committee objected to the use of the term "free blood" in the publicity of the American Red Cross. It has not been the practice of American Red Cross to use the words "free blood" in publicity regarding the National Blood Program. However, it must be generally and clearly understood that blood and blood derivatives are made available by the Red Cross to physicians and hospitals without cost to them. While it is expected that they will collect from the recipient expenses incident to the administration of that blood, they will not collect from him payment for material for which they have paid nothing to the Red Cross.

It is unthinkable that the Red Cross should sell to physicians and hospitals the blood and blood derivatives that are the result of donations freely given it for the alleviation of distress and suffering of persons who need that blood or the substances which come from it. It is equally unthinkable that physicians and hospitals should sell to recipients that which they have received from the Red Cross without cost to them. There would be no Red Cross blood donors and no Red Cross blood program if those who were asked to give their blood were informed that the blood which they had given or the substances which came from it were to be sold to physicians and hospitals who in turn would sell these products to the persons whose lives would be in jeopardy without them.

Washington Letter

(From Our Regular Correspondent)

July 28, 1948.

Critique of Brookings Health Report Published

The Senate Committee on Labor and Public Welfare has begun distribution of a seventeen page critique of the Brookings Institution report, published earlier this year and entitled "The Issue of Compulsory Health Insurance." Prepared by Michael M. Davis, chairman of the Committee on Research in Medical Economics, and Dewey Anderson, executive director of Public Affairs Institute, the analysis was printed and is being distributed by the Senate committee at the behest of two of its members who are proponents of national health insurance, Senators James E. Murray and Claude Pepper. Main points of the Davis-Anderson review are summarized as follows: (1) The Brookings report does not present evidence justifying its condemnation of compulsory health insurance, nor does it recognize "that most of the difficulties alleged against compulsory health insurance are faced and must be solved by voluntary plans also"; (2) it does not face squarely the problem of unpredictable sickness costs; (3) the Brookings conclusion that the public should depend on voluntary health insurance does not explain how obstructions to enrollment of great masses of population in such plans are to be eliminated; (4) advocacy of the "means test," by which persons unable to pay dues in voluntary plans would receive charity, tax-supported medical care, is denounced as "neither politically valid nor decently human"; (5) finally, according to Davis and Anderson, "The Issue of Compulsory Health Insurance" (written by George W. Bachman and Lewis Meriam) begs the question by devoting considerable space to mortality and morbidity statistics which have little or no bearing on the issue of health insurance. It is understood that only three hundred copies of the Davis-Anderson review have been printed by the Senate committee, but the authors' respective organizations will issue their own printings. The Senate's limited edition bears on its cover a notice: "opinions expressed herein should in no way be construed as representing the official views of either the Subcommittee on Health or the Senate Committee on Labor and Public Welfare."

First Inter-American Conference for Rehabilitation of Cripples

Michael J. Shortley, director of the Office of Vocational Rehabilitation, Federal Security Agency, served as chairman of the United States delegation to the First Inter-American Conference for Rehabilitation of Cripples, held in Mexico City July 18-24. Other members of the official group, appointed by the State Department, included Dr. Henry H. Kessler, representing the National Council on Rehabilitation; Col. Harold B. Luscombe, chief of physical medicine at William Beaumont General Hospital; Comdr. Thomas J. Canty, Mare Island (Calif.) Naval Hospital, and Lieut. Col. Benjamin A. Strickland Jr., chief of the physical medicine consultants' division in the Army Surgeon General's Office.

Shellfish Bacteriology Laboratory Established

U. S. Public Health Service has announced establishment at the Woods Hole (Mass.) Oceanographic Institution of a laboratory for investigations of shellfish bacteriology. One of its first projects will be a comparative study of organisms, such ascoliform bacteria, which have been used to ascertain pollution of shellfish-growing waters. Reevaluation of technical information on which sanitary standards are based will be one of the laboratory's duties. Studies will be undertaken, under controlled conditions, on the common varieties of edible shellfish: oysters, hard and soft clams and mussels.

GOVERNMENT SERVICES

ARMY

PHARMACY RESERVE UNIT

A Pharmacy Reserve Officers Training Corps unit will be in operation this fall at the University of Minnesota under the direction of Major Leonard P. Zagelow of the U. S. Army. Any man between 18 and 27 years of age who can meet college requirements is eligible to enter the new program. Each student is required to spend one hour per week in military instruction, in addition to the regular pharmacy credits for the four years and to attend an army camp for six weeks between his junior and senior years. At the completion of the program he is awarded a commission in the Reserve Officers Corps, and during his junior and senior years receives compensation amounting to about $24 a month.

LECTURES AT INSTITUTE OF PATHOLOGY

Dr. Hartwig Kuhlinbeck, Woman's Medical College, Philadelphia, lectured on "Nephrogenic Adenoma of the Urinary Bladder" on June 23. On June 24, Dr. Henry Pinkerton, St. Louis University School of Medicine, lectured on "Experimental Work on Cancer with Particular Reference to Chemotherapy." On June 25, Dr. Herman Becks, the Hooper Foundation, University of California, lectured on "Nutritional Studies in Development of the Mandible and Maxilla."

PERSONALS

Lieut. Col. Helen C. Burns, the first woman to receive an Army commission as a dietitian, has retired from the Army after twenty years of service. Colonel Burns was Director of Dietitians in the Surgeon General's Office during the recent war.

Mr. Joseph A. Groesbeck, chief of the library's acquisition division, left on a two month mission to Japan on July 6, to acquire Japanese medical literature lacking in the library's collections and to reopen exchange relationships with Japanese institutions.

BODY WEIGHT AND MAXIMUM STATURE

The Quartermaster Corps has completed an anthropometric survey of Army men and women to determine the average weight and measurements for different groups. The purpose was to obtain data with which to revise the range of clothing sizes issued and to prepare for the induction of young men under the new draft law. Studies were made of more than 17,000 men between 17 and 26 years of age, some of whom were being inducted into the service and others being discharged from the service. The average mean stature of the 17-year-olds was 67.71 inches (172 cm.) and the average weight 139.5 pounds (63.3 Kg.). After one or two years of service in the Army, these averages increased. The mean maximum stature of 68.51 inches (174 cm.) was attained at the age of 21; however, after the age of 19 years the average increase was only 0.1 inch (0.25 cm.). The chest circumference for the 17-year-olds averaged 34.5 inches (87.6 cm.) and for the 26-year-olds 36.76 inches (93.4 cm.). The neck, judging from these measurements, appears to stabilize in the twenty-fourth year. Of the extremities, the only one which showed any increase after 17 years of age was in the breadth of the hands, which showed an average increase of 2 per cent between 19 and 22 years of age.

The Quartermaster data for the 17-year-olds were compared with similar data obtained by the Brush Foundation over a ten year period at Western Reserve University, Cleveland. The first period of the Brush Foundation studies covered less than a thousand persons representing the economic group for which the average stature at age 17 was 69.48 inches (176.5 cm.) and the mean average weight 147.5 pounds (66.9 Kg.). Since the Army series at age 19, after one or two years of service, show a mean weight averaging about that of the Brush series, the Quartermaster Corps concludes that military diet and environment are beneficial to the group. The study indicates also that the general population is capable of attaining at least as much weight as the "well born" persons, providing it is given the opportunity.

NAVY

RESERVE OFFICERS NEEDED FOR TRAINING DUTY

Naval Reserve medical officers are needed for fourteen day training duty at stations of the Naval Air Reserve Training Command of the Fourth Naval District Headquarters in Philadelphia. Interested reserve officers on inactive duty may obtain information from the office of the Commandant, Fourth Naval District, Naval Base, Philadelphia 12, Pa.

OFFICERS APPROVED FOR POSTGRADUATE TRAINING

The Advisory Board of the Bureau of Medicine and Surgery recently approved the following officers for postgradaute training:

Comdr. Harold L. Baxter (MC), U.S.N., Fellowship in Neurology, Jefferson Medical School, Philadelphia.

Comdr. George L. Calvy (MC), U.S.N., Teaching Fellowship in Preventive Medicine Division, Western Reserve University School of Medicine.

Comdr. Karl V. Kaess (MC), U.S.N., Residency in Dermatology and Syphilology, Naval Hospital, Philadelphia.

Comdr. Edward W. Pinkham (MC), U.S.N., Residency in Surgery, Naval Hospital, Philadelphia.

Comdr. Robert S. Poos (MC), U.S.N., course of instruction in preventive medicine, University of California.

Lieut. Comdr. Wilbur S. Lummis Jr., (MC), U.S.N., Residency in Internal Medicine, Northwestern University and Passavent Hospital, Chicago.

Lieut. Comdr. Leo S. Madlen (MCR), U.S.N.R., Residency in Internal Medicine, Naval Hospital, San Diego, Calif.

Lieut. Comdr. George S. Watkins (MC), U.S.N., course in preventive medicine, Johns Hopkins University.

Lieut. George C. Beattie (MC), U.S.N., Fellowship in Adult Orthopedics, Lahey Clinic, Boston.

Lieut. Boyd K. Black (MC), U.S.N., Fellowship in Pathology, Washington University, St. Louis.

Lieut. John H. Cheffey (MC), U.S.N., to continue course in children's orthopedics at the Alfred I. DuPont Institute, Wilmington, Del.

Lieut. Charles B. Newton (MC), U.S.N., Residency in Internal Medicine, Naval Hospital, Chelsea, Mass.

Lieut. (jg) Thomas C. Deas (MC), U.S.N., Residency in Anesthesiology, University Hospital, Augusta, Ga.

Lieut. (jg) Robert J. Fleischaker (MC), U.S.N., Residency in Surgery at a Naval hospital.

Lieut. (jg) Dean W. Hales (MCR), U.S.N.R., course in otolaryngology, Graduate School of Medicine, College of Medical Evangelists, Los Angeles.

Lieut. (jg) Alan D. Watson (MC), U.S.N., Residency in Dermatology and Syphilology, Naval Hospital, St. Albans, L. I., N. Y.

THE END OF AN OLD NAVY HOSPITAL

The one hundred and ten year old Brooklyn Naval Hospital with its thirty-seven buildings ceased to be a hospital June 30. The old plant will be known henceforth as the "United States Naval Receiving Station Annex, Brooklyn." The patients were transferred to the Navy's more modern hospitals. During the recent war, the hospital cared for 65,197 Navy men and women and their dependents. At the opening of the Civil War, this hospital had only two medical officers on its staff, while during World War II there were 107 medical officers, 170 nurses and 400 Medical Corps men on its staff.

REQUEST OFFICER BE ALLOWED TO REMAIN AT GUAM HOSPITAL

The Secretary of the Navy has received a petition from the people of Guam requesting that Capt. H. C. Oard (MC) be allowed to remain "with us" as medical officer in command at the Guam Memorial Hospital for at least one year. The petition unanimously adopted at a joint session of the Guam Congress June 5 and signed by E. T. Calve, Speaker of the House of Assembly and B. J. Bordallo, President of the House of Council, read in part as follows: "Captain Oard has the unqualified confidence, support and friendship of the Guamanian people and it is earnestly requested that he be allowed to remain with us so that the completion of his work may result in great benefit to all."

NEW REGULAR OFFICERS

The following graduates of the Navy's V-12 program have accepted appointments in the medical corps of the regular Navy: Lieutenants (jg) Samuel A. Heaton, Augusta, Ga.; Walter G. Leonard, Norton, Mass.; Harold T. Meryman, Dublin, N. H.; William M. Strunk, Mifflinsburg, Pa.; John S. Walker, Brevard, N. C., and Ernest F. Wallner Jr., Wauwatosa, Wis.

FLIGHT SURGEONS

The Naval School of Aviation Medicine at Pensacola, Fla., on June 18 graduated and designated as flight surgeons the following officers. The principal speaker at the ceremony was Capt. William Sinton, Commanding Officer of the Naval Air Station.

Raymond J. Adams, Lewiston, Idaho
Jack W. Barrett, Miami, Fla.
Robert L. Bauer, Chester, Pa.
Robert L. Burdick, Maple Springs, N. Y.
C. Walter Coolidge, Savannah, Ga.
Henry D. Crane Jr., Belmont, Mass.
Carroll M. Elmore, Rupert, Idaho
Beverly O. Evans, Helena, Ark.
George M. Ewing, Brookfield, Mo
Edward C. Gresham, Hampton, Ark.
Robert D. Hunt, Endicott, N. Y.
Alvin C. Jensen, Mt. Pleasant, Utah
Edward V. Johnston, Wilmette, Ill.
Frank F. Kalchuk, Hempstead Gardens, L. I., N. Y.
Leon M. Kruger, Norfolk, Va.
Richard E. Luehrs, Merrill, Ore.
Dennis P. McCarty, Delaplane, Va.
Charles C. Muehe, Chicago
Charles Pierson, Nutley, N. J.
Lockland V. Tyler Jr., Jacksonville, Fla.

PUBLIC HEALTH SERVICE

SURVEY OF SANITATION

A survey of the sanitation needs of the United States recently made by the United States Public Health Service is now available in printed form. This survey, the Federal Security Agency reports, is the first attempt on a national scale to evaluate the needs of this country for sanitation facilities on the basis of actual field investigation. According to the report, more than 6,000,000 persons in towns and cities need new sewerage systems, while 79,000,000 others need improvements to sewerage systems. More than 2,000,000 persons, it is stated, living in communities of 200 or more persons, have no community water supply systems, and 79,000,000 persons have systems that need improvements. The total cost of needed water supply and waste disposal facilities was estimated at $7,834,581,000. More than 27,000,000 persons in rural areas need new or improved water supply, and more than 33,000,000 in such areas have unsatisfactory sewage disposal systems. To remedy this condition, the report states, the nation needs an additional 2.2 billion dollars' worth of water works; 3.7 billion dollars of sewerage facilities; 166 million dollars of garbage facilities, and 1.6 billion dollars of all types of sanitation facilities for rural homes.

Copies of the survey report may be purchased at 15 cents each from the Superintendent of Documents, Washington, D. C.

EMERGENCY PLANNING UNIT

The Federal Security Administrator announces the establishment of a Health Emergency Planning unit in the U. S. Public Service under the direction of Dr. Norvin C. Kiefer. The new unit will draw plans for more comprehensive public health catastrophe services to be offered in response to peacetime emergency requests from states. The unit will co-operate with the National Security Resources Board, the Office of Civil Defense Planning of the National Military Establishment, the Military Services, and State Health Department, as well as professional and voluntary organizations, to plan a coordinated program for safeguarding public health during a national emergency.

DR. MEADER APPOINTED DEPUTY CHIEF

The Director of the National Cancer Institute announces the appointment of Dr. R. G. Meader as Deputy Chief of the Cancer Research Grants Branch of the Institute. He will be responsible for scientific reviews of applications for cancer grants, for maintaining contact with investigators in the field and for analyzing the grant-in-aid program of the Institute in relation to programs of other agencies supporting research in cancer. Dr. Meader received a Ph.D. degree at Yale University. He was formerly assistant professor in biology and in anatomy and a lecturer in anatomy at Yale.

MISCELLANEOUS

ROTATING INTERN AND PSYCHIATRIC RESIDENCE

The U. S. Civil Service Commission will conduct an examination for filling medical officer positions in St. Elizabeth's Hospital, Washington, D. C. Medical officers (rotating intern) are paid $2,200 for the first year and $2,400 for the second year. Medical officers (psychiatric resident) are paid from $2,400 to $4,100 a year, depending on the amount of approved graduate training that the applicant has completed. Appointments are open for July 1, 1949. To qualify for internship, applicants must be third or fourth year students in an approved medical school; however, they may not enter on duty until they have completed their full course of study. Applicants for psychiatric residency must be graduates of an approved medical school and in addition must have completed an approved internship or now be serving such an internship. No written test is required for these positions. Application forms may be obtained from the U. S. Civil Service Commission, Washington, D. C., from post offices and from Civil Service regional offices.

AWARDS AND COMMENDATIONS

Dr. George G. Deaver

The President of the United States has awarded the Medal for Merit to Dr. George G. Deaver, Professor of Clinical Rehabilitation and Physical Medicine at New York University College of Medicine. The citation read in part as follows: Dr. Deaver, a pioneer and researcher in the field of rehabilitation undertook a training program for the Army Air Forces in October, 1943, giving unstintingly of his time in teaching his techniques of restoration and rehabilitation. He served as Consultant to The Air Surgeon, as well as consulting with the Army, Navy, and Veterans Administration in the field of rehabilitation, and aid them not only with individual patients, but also in setting policy for their over-all programs. As a result of these contributions, many lives were saved, suffering was diminished and countless men were returned to duty or productive places in civilian life.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

CALIFORNIA

Personal.—The Alumni Association of the College of Medical Evangelists, Loma Linda, dedicated the March issue of its journal to the late Dr. Percy T. Magan, president of the college from 1928 to 1942 and president emeritus from then until the time of his death, Dec. 16, 1947.—Robert B. Witham, administrator of the Scripps Memorial Hospital, La Jolla, died July 4 of myocardial infarction.

Fellowship in Ophthalmology.—Alumnae of the Upsilon chapter of the Delta Gamma Sorority of Stanford University have presented the university $41,000 for a fellowship in ophthalmology. The gift represents proceeds of the sale of the sorority house following dissolution of Stanford sororities in 1944. Presentation of the gift, which fits into a national Delta Gamma alumnae project for the care and prevention of blindness, followed approval by the Superior Court of Santa Clara County of the dissolution of the Stanford Delta Gamma Association as a corporation. Sorority gifts also included a contribution to the building fund of the Palo Alto Society for Blind.

CONNECTICUT

Rural Health Conference.—A Rural Health Conference on August 11 is being arranged by the state medical society's committee as a feature of the annual Farm and Home Week at the University of Connecticut, Storrs. Mrs. Charles Sewell, Chicago, director of the Associated Women of the American Farm Bureau Federation, and Dr. Joseph H. Howard, Bridgeport, chairman of Connecticut's Commission on the Care and Treatment of the Chronically Ill, Aged and Infirm, will be the principal speakers.

Training Program in Cancer Control.—Yale University School of Medicine will establish in September a long range training program for cancer control officers. The Department of Public Health will work with the section on oncology of the department of surgery to provide a one year course for personnel who will specialize in the administration of programs caring for those with cancer. To head the new section on cancer control the university has appointed Dr. Edward M. Cohart, formerly cancer consultant, U. S. Public Health Service, as associate professor of public health. Establishment of the section was made possible by a grant of $24,000 from the U. S. Public Health Service National Cancer Institute. Three classes of students will be eligible for the instruction at Yale beginning in September: (1) physicians who have had at least two years in medical practice; (2) graduate nurses or persons who hold a bachelor's degree and possess at least three years of experience in medical or dental care or public health work; (3) special students who are not candidates for a degree, but who possess an appropriate background of training and experience. There will be cooperation with many agencies engaged in diagnosis, treatment, education and research in cancer. Information may be obtained from Dr. Edward M. Cohart, Cancer Control Section, Department of Public Health, Yale University School of Medicine, 310 Cedar Street, New Haven 11.

ILLINOIS

Deaths from Leprosy.—Among the unusual causes of death occurring in Chicago in 1947 was leprosy (2 deaths), according to the Illinois Department of Public Health. Since 1921, the first year for which accurate vital records for the state are available, there have been 6 deaths from the disease in Illinois. One death was reported in each of the years 1945, 1928, 1924 and 1922; all occurred in Chicago.

State Society Resumes Postgraduate Conferences.—The council of the Illinois State Medical Society, for the second time, has authorized twelve postgraduate conferences. The Seventh Councilor District has requested the first conference, September 16, in Centralia, with the Marion County Medical Society as host. The session will open with a luncheon at the Pittenger Hotel. The following program will be presented: Israel Davidsohn, Chicago, Clinical Applications of the Rh Factor; Hugo R. Rony, Chicago, Hormone Preparations and Their Uses; Warren H. Cole, Chicago, Surgical Lesions of the Stomach; Lester D. Odell, Chicago, Cesarean Section; Noel G. Shaw, Evanston, Feeding Problems in Infants; Allergic Conditions in Children, and Treatment of Congenital Syphilis with Penicillin. In the evening, Dr. Robert E. Britt, St. Louis, will discuss "Psychosomatic Medicine."

Chicago

Another Gift to Allergy Unit.—The Asthmatic Children's Aid has presented $10,000 to the University of Illinois Colleges of Medicine and Pharmacy for investigative work in allergy. This group has contributed almost $40,000 to the University of Illinois' Allergy Unit since it was established in November 1944.

Graduate Course in Otolaryngology.—The department of otolaryngology at Northwestern University Medical School will give a course of graduate training in the basic sciences of the ear, nose and throat, beginning in October. Each course lasts about nine months and will be divided info about equal portions of didactic, laboratory and clinical study.

Library to Abstract Atomic Energy Articles.—The Atomic Energy Commission and the John Crerar Library of Chicago have signed a contract by which the library will abstract scientific books and periodicals necesary to the research on atomic energy being done under the sponsorship of the commission. The commision will reimburse the library for all costs. The program calls for a special staff of experts to be established by the library to review the 3,500 periodicals received for material pertinent to research on atomic energy, translate it when necessary, abstract it and make it immediately available to the commission for distribution to its affiliated research laboratories. The interests of the research staff will cover largely the peacetime uses of atomic energy in medicine, metallurgy, agriculture and the like. The staff will also use the 700,000 books in the library in making searches on special subjects submitted by the commission. The library was established in 1895 under the will of John Crerar, who directed the establishment of a free public library. In the half century intervening, the library has built up its own collection of books and periodicals in science, technology and business and has acquired by purchase and gift many complete specialty collections. The Board of Directors of the library is headed by Britton I. Budd, president of the Public Service Company of Northern Illinois.

MAINE

State Medical Election.—At the annual meeting of the Maine Medical Association in Poland Springs, June 20-22, Dr. Forrest B. Ames, Bangor, was installed as president; Dr. Ralph A. Goodwin, Auburn, was chosen president-elect; Dr. C. Harold Jameson, Rockland, chairman of the council, and Dr. Frederick R. Carter, Portland, secretary-treasurer.

MASSACHUSETTS

Dr. Williams Goes to University of Washington.—Dr. Robert H. Williams, assitant professor of medicine at Harvard Medical School, Boston, became professor and executive officer in the Department of Medicine, University of Washington School of Medicine, Seattle, July 1. After receiving his M.D. degree from Johns Hopkins University School of Medicine, Baltimore, in 1934, he was a research fellow at Massachusetts General Hospital and served on the staffs of the Thorndike Laboratory and Boston and City hospitals. He joined the Harvard Medical faculty in 1940 as an instructor in medicine, and became an associate professor in 1944.

MICHIGAN

Pollen Survey.—The eighth annual ragweed pollen survey of the Michigan Department of Health began in fifty-three cities of the state on July 15. A new plan of operation is expected to make pollen counts for each area available on a day to day basis from the local health officers. Copies of the new 1947 survey report and pollen map, showing areas of greatest and least pollen concentration, are available without charge from the Michigan Department of Health, Lansing 4, Michigan.

Detroit Cancer Center.—All cancer activities in the metropolitan Detroit area are to be housed in the Detroit Cancer Center on John R and Hancock streets, which will also provide laboratory space for the Detroit Institute for Cancer Research. The Southeastern Michigan Division of the American Cancer Society, representing Macomb, Oakland and Wayne Counties, will have headquarters in the building. This organization has eight cancer detection centers operating in various Detroit hospitals and plans to open an additional center in the new headquarters. The center also furnishes facilities for an enlarged educational program. The building is owned by the Michigan Cancer Foundation. The Detroit Cancer Center is the result of a greatly expanded cooperative program that has been developed in the last few years between scientific and lay groups. It is planned to coordinate its research program of nearly two hundred projects with that now supervised by the National Research Council and subsidized by the American Cancer Society.

MISSOURI

Regional Blood Program.—The Greene County Community Blood Donor Service, sponsored by the local chapter of the American Red Cross and the Greene County Medical Society, became a regional service covering twenty-eight counties July 15. Dr. James R. Amos, former Greene County Health Officer, is medical director. A "bloodmobile" will make regular visits to all communities in a one hundred mile radius of Springfield, which is said to be the second community in the Midwest and the first in Missouri to establish a regional blood service program. The Greene County Medical Society Blood Donor Service Committee will remain active and act in an advisory capacity on medical problems.

MONTANA

Personal.—Dr. Richard C. Monahan, Butte, was elected president of the Montana State Board of Health at its meeting in March, and Dr. Burton K. Kilbourne, Helena, who has been secretary of the board and executive officer, was reelected for a term of two years.——Dr. Edmund A. Welden, Lewistown, a member of the State Board of Medical Examiners for many years, was recently elected president of the board, succeeding Dr. Patrick E. Kane, Butte.

Lectures on Cancer.—Dr. John I. Brewer, associate professor of gynecology at Northwestern University Medical School, Chicago, has completed a series of five lectures to physicians in Montana, speaking at Miles City, Billings, Lewistown, Bozeman and Helena on differential diagnosis and early cancer detection. These lectures were made available to physicians by the Montana State Board of Health, Montana Medical Association and the Montana Division of the American Cancer Society. Additional specialists on cancer will be brought to Montana to speak from time to time throughout the year.

NEW JERSEY

Emergency Medical Service.—The Monmouth County Medical Society on July 8 began a twenty-four hour a day emergency service that will be linked by telephone with all police, fire and first-aid stations in the county. The service is said to be the first in the country instituted on an areawide basis.

Service for the Chronically Ill.—The Essex County Chronic Ill Service, established in Newark, will maintain a registry for families, doctors and organizations caring for the chronic ill and will develop additional visiting nurse facilities. The organization also will assemble statistics, further legislation for aid to the chronically ill and serve as an advisory center. The service is patterned after those in Philadelphia and Chicago.

NEW YORK

Postgraduate Instruction.—The Medical Society of the State of New York, with the cooperation of the New York State Department of Health, has arranged postgraduate instruction for the Tompkins County Medical Society, September 20, 8:30 p. m., at the Tompkins County Memorial Hospital, Ithaca. Dr. Kristian G. Hansson, Cornell University Medical College, New York, will speak on "Prescription in Physical Medicine."

County Society Appoints Executive Secretary.—The Medical Society of the County of Monroe has appointed Miss Helen R. Guntert, executive secretary of the Rochester Academy of Medicine, as its executive secretary. She will head the new executive department created by the society and serve as managing editor of its county bulletin. The society has opened enlarged quarters on the second floor of the academy building.

New York City

Personal.—Dr. Henry M. Scheer has been elected president of the New York University College of Medicine Alumni Association.—Dr. Golden Selin has been appointed assistant pathologist at the Hospital for Joint Disease, replacing Dr. Louis Lichtenstein. Dr. Selin was formerly an instructor in pathology at the New York Medical College.—Dr. Elaine P. Ralli, associate professor of medicine, New York University College of Medicine, on April 29 was reelected president of the Women's Medical Association of New York City.—Dr. Claude W. Munger, director of St. Luke's Hospital for eleven years, has resigned and will be succeeded by Dr. Lloyd H. Gaston, who has been assistant director.—The board of trustees of the New York Polyclinic Medical School and Hospital has named one of the operating rooms "The Brennan Operating Room" in honor of Dr. Robert E. Brennan, director of surgery, who has been associated with the institution for many years.

Forum on Venereal Disease Control.—Lectures and demonstrations on the diagnosis, treatment and management of venereal diseases will start at the New York City Department of Health, September 18. There will be fourteen weekly meetings, on the following Saturdays, presided over by experts in various fields of venereal disease control. Sessions will start at 10:30 a. m. and will be held in the second floor auditorium at 125 Worth Street, Manhattan. The lecture topics have been selected for physicians, social workers, nurses, laboratory workers, industrial medicine personnel and teachers. No registration or fee is required.

Health Education Institute.—The New York University School of Education will begin a series of annual health education institutes August 16-September 3. The first institute will be on problems in alcohol education. The Alcohol Education Institute lecturers will include: Dr. Ralph S. Banay, research associate, Columbia University; Dr. I. Jay Brightman, Brooklyn, division of medical services, New York State Department of Health; Brigadier General Chester R. Brown of the Salvation Army; Anton J. Carlson, Ph.D., professor of physiology, University of Chicago; Dr. Harvey B. Haag, dean, Medical College of Virginia, Richmond; Mr. Joseph Hirsh, Research Council on Problems of Alcohol, New York; Edward J. McGoldrich Jr., City of New York Bureau of Alcohol Therapy; Dr. Mary Jane Sherfey, Cornell University Medical College, New York, and Rev. Alson J. Smith, Roxbury Methodist Church, Stamford, Conn.

OHIO

Dr. Ernstene Appointed Head of Department.—Dr. A. Carlton Ernstene, Cleveland, has been appointed head of the division of medicine at the Cleveland Clinic. Dr. Ernstene joined the clinic staff in 1932 and for many years has been head of the section on cardiovascular disease. He received his medical training at the State University of Iowa College of Medicine, Iowa City, and was a member of the faculty of Harvard Medical School, Boston, from 1927 to 1932. He was recently elected president of the Cleveland Cardiovascular Society and is a director of the Academy of Medicine of Cleveland. During World War II he was on active duty with the Navy in the South Pacific area.

PENNSYLVANIA

Cancer Control Appointment.—Dr. Leverett D. Bristol, Augusta, Maine, has been appointed chief of the cancer control division of the state department of health. He is a graduate of Johns Hopkins University, Baltimore, has a public health degree from Harvard University, Boston, and organized the state cancer committees in North Dakota and Maine.

Philadelphia

Professor of Ophthalmology at Jefferson.—Dr. Arno Emerson Town, clinical professor of ophthalmology, New York University College of Medicine, was appointed professor of ophthalmology at the Jefferson Medical College on July 1, succeeding Dr. Charles E. G. Shannon, whose retirement becomes effective on that date. Dr. Town graduated from Jefferson in 1926. He also received a Master of Medical Science degree in ophthalmology from the University of Pennsylvania School of Medicine in 1931. During the last war he served as a commander in the United States Naval Reserve as ophthalmologist at the United States Naval Medical Center, Bethesda, Md., and aboard the hospital ship *U. S. S. Benevolence*.

Medical Center Plans Announced.—Plans for a $10,000,000 medical center at the University of Pennsylvania Medical School and Hospital have been announced. The medical center will include a nine story outpatient building, an eleven story inpatient building and a nine story nurses' home to be built at an estimated cost of $8,500,000. An additional $1,500,000 will be required by the department of medicine to support teaching and research. A conditional contribution of $1,000,000 from the Donner Foundation, Inc., will go toward the construction of a group diagnostic outpatient clinic, provided the university starts construction on the building by May 1949. The campaign for the medical center is part of a $22,000,000 development program for the university, covering eleven of its schools and departments.

GENERAL

Board Appoints Assistant Secretary.—The American Board of Obstetrics and Gynecology announces that it has established the position of assistant secretary and that Dr. Robert L. Faulkner, Cleveland, has been appointed to this new post. All communications should be addressed as heretofore to Paul Titus, M.D., Secretary, 1015 Highland Building, Pittsburgh 6.

National Medical Association Meeting.—The annual meeting of the National Medical Association will be held in New York August 16-20 with headquarters at Wadleigh High School and under the presidency of Dr. J. A. C. Lattimore, Louisville, Ky. After the opening meeting the scientific assembly will hold section meetings at hospitals of the city. The Women's Auxiliary will meet in conjunction with the association.

Atomic Energy Fellowships.—For consideration at the next meeting of the Atomic Energy Commission Postdoctoral Fellowship Board in the Medical Sciences in late September, applications must be sent to the office of the board in the National Research Council before Sept. 1, 1948. Inquiries should be addressed to the Division of Medical Sciences, National Research Council, 2101 Constitution Avenue, N.W., Washington 25, D. C.

Appointed Secretary of Pharmacopoeil Convention.—The board of trustees of the United States Pharmacopoeial Convention have reelected Robert L. Swain, New York, and Adley B. Nichols, Philadelphia, as chairman and secretary. Mr. Nichols fills a vacancy caused by the resignation of Lewis E. Warren, Ph.C., who has served the convention as secretary since 1930. Dr. Warren has retired from government service where he had been a chemist for many years. The convention will meet at the Statler Hotel, Washington, D. C., May 8-10, 1950.

Dr. Page Goes to Arabia.—Dr. Robert C. Page, formerly assistant medical director of the Texas Company, has been appointed medical director of the Arabian American Oil Company and has left for Arabia, where the Arabian American Oil Company has new base hospital. Dr. Page is a graduate of Syracuse University College of Medicine, Syracuse, 1933, and was formerly associated with the Mayo Clinic, Rochester, Minn. During World War II he served as a major in the U. S. Army Medical Corps and engaged in malaria control in the South Pacific.

Red Cross Board of Governors.—The American Red Cross, at its meeting in San Francisco in June, elected Mrs. Arthur H. Vandenberg to fill the unexpired term of the late Judge Stanley L. Orr, Cleveland. Those elected to three year terms on the board were: Mrs. J. K. B. Hare, Pittsburgh, and Harold A. Young, Little Rock, Ark. Those reelected to the board were Clarence Bamberger, Salt Lake City; Sheldon Coleman, Wichita, Kan.; John B. Hollister, Cincinnati; Charles H. Kellstadt, Chicago; Howard S. Wilson, Lincoln, Nebraska; Edward Dana, Boston; Junius P. Fishburn, Roanoke, Va., and Robert N. Haskell, Bangor, Maine.

Meeting of Occupational Therapists.—The American Occupational Therapy Association will hold its thirty-first annual convention at the Hotel Pennsylvania, New York City, September 7-11. Among the speakers are: Dr. Howard A. Rusk, New York; Mr. Holland Hudson, director of rehabilitation service, National Tuberculosis Association; Luther Woodward, field consultant to the National Committee for Mental Hygiene; Dr. Leland E. Hinsie, New York, assistant director, New York State Psychiatric Institute and Hospital. On Septmeber 10 and 11, a teaching institute will present recent developments and technics in the treatment of neuropsychiatric conditions. Trips to hospitals and other institutions in New York City and surrounding areas on September 9 and 10 have been arranged.

Appointments at The Rockefeller Institute.—The board of scientific directors of the Rockefeller Institute for Medical Research announces the promotion of Alfred E. Mirsky, Ph.D., and D. Wayne Woolley, Ph.D., from associate member to member, and the appointment of Dr. Reginald M. Archibald as member. Dr. Maclyn McCarty has been promoted from associate to associate member. New appointments include: associate—Dominic Dziewiatkowski; assistants—Margaret Oakley Dayhoff, Jacques Genest, Herbert Jaffe, Edwin D. Kilbourne, George E. Palade, Stanfield Rogers, Chandler A. Stetson Jr., Harrison F. Wood, and Mr. R. Barclay McGhee. The board also announces that Donald D. Van Slyke, who has reached the age of retirement, has been made member emeritus of the institute.

Dysentery Registry.—The Pan-American and International Dysentery Registry has a two-fold objective for 1948: (1) the prevention of acute intestinal infections; (2) the accumulation of data on chronic ulcerative colitis. It is again urging control of the cleanliness of food and foodhandlers in cities, summer resorts and on vehicles of transportation; proper disposal of sewage and supervision of water supplies; fly control; prompt reporting and epidemiologic investigation of all infectious diarrheas. A motion picture, "From Hand to Mouth," may be borrowed from the Registry without cost by any teaching institution. Consultative facilities on clinical, epidemiologic, bacteriologic or pathologic problems are also available at the Registry without cost. The Registry is appealing for accurate follow-up data for one year on all cases of acute bacillary dysentery.

Study of Physical Effects of Swimming.—A tri-state survey of Lake Michigan waters with special reference to bathing is being made by the Illinois, Indiana and Wisconsin state health departments and local governmental health agencies. coordinated by the U. S. Public Health Service. The study will extend from Milwaukee, Wis., to Michigan City, Ind. The survey aims:

1. To determine the physical, chemical and bacteriologic conditions of the waters tributary to and at bathing areas.
2. To investigate the physical factors which influence the changes in water quality.
3. To study the effects of bathing loads on water quality.
4. To secure epidemiologic data on diseases attributable to bathing.

In each area 1,000 families will be asked to record unusual reactions to bathing or any symptoms of illness such as eye, ear, nose, throat, skin infections or gastrointestinal upsets. Medical students and public health nurses began a house to house canvas June 28.

National Employ the Physically Handicapped Week.—The President of the United States has appointed a committee on National Employ the Physically Handicapped Week composed of outstanding Americans who are helping to spearhead the drive for employment of the handicapped. The efforts of the committee are expected to increase public education and information on the subject. The chairman of the committee is Vice Admiral Ross T. McIntire, U.S.N. (retired), and the vice chairman is Merle E. Frampton, LL.D., New York, who also is head of the executive committee. Many of the subcommittees have already held meetings, and among the matters under consideration were awards of merit to employers who cooperate in the employment of impaired workers and formation of labor and management employment institutes at a number of colleges throughout the country. The chairman of the medical committee is Dr. Carl M. Peterson, Secretary of the Council on Industrial Health of the American Medical Association, Chicago; the vice chairman is Dr. George Morris Piersol, Secretary General, The American College of Physicians, Philadelphia.

Poliomyelitis in the United States.—According to the U. S. Public Health Service for the week ended July 10, a total of 513 cases of poliomyelitis was reported, as compared with 362 the previous week. The largest number of cases continue to be reported in North Carolina, with 131, California, 92, and Texas, 89, reported 37 per cent of the total, as compared with 64 per cent week of July 3. In North Carolina the counties from north to south in the central and west central parts of the state were apparently bearing the brunt of the epidemic; the extreme western counties and the coastal areas have reported only a few scattering cases. In Texas the disease was first prevalent in counties in the southern and south coastal areas, but more recently a shift was apparent from South Texas and the coast to the central and northern parts of the state. Although no epidemic incidence has been reported in other states, an increased proportion of the total cases is being reported from other than the three states mentioned. In addition to these three states, only seven other states reported more than 10 cases during the week, as follows (figures for week of July 3 in parentheses): Oklahoma 21 (3), Iowa 19 (0), Virginia 17 (2), Ohio 15 (14), Illinois 12 (6), New York 11 (7) and Nebraska 11 (8). To date only 14 cases have been reported in the six New England states—8 in Massachusetts, 4 in Connecticut and 2 in Vermont. The total to date for the country as a whole is 2,881, as compared with 1,294 in 1947, 2,165 in 1946 and a five year median of 1,329 for the corresponding period.

CORRECTION

Postgraduate Courses.—On page 722 of THE JOURNAL for June 19, 1948, the courses offered by the Graduate School of Medicine of the College of Medical Evangelists were incorrectly stated. The graduate courses offered are basic science courses in internal medicine, general surgery, gynecology and obstetrics, urology and otolaryngology. The fee for each of these courses is $700.

Deaths

George Tully Vaughan ⊕ professor of surgery emeritus, Georgetown University School of Medicine, Washington, D. C., died, April 26, aged 88, of cerebral hemorrhage. Dr. Vaughan was born in Arrington, Va., June 27, 1859. He graduated in medicine from the University of Virginia Department of Medicine, Charlottesville, in 1879 and from the Bellevue Hospital Medical College in New York in 1880, then did graduate work at the New York Polyclinic, University of Berlin and Jefferson Medical College in Philadelphia. After a period of private practice, he entered the U. S. Marine Hospital Service in 1888, serving in this country and abroad until he resigned in 1906, after having reached the grade of assistant surgeon general. During the Spanish-American War he was loaned to the U. S. Army and served as major and brigade surgeon of the Seventh Army Corps at Jacksonville, Fla.; he was a navy surgeon at Vera Cruz in 1914, and again during World War I, serving aboard the *U.S.S. Leviathan.* Dr. Vaughan was appointed to the chair of principles and practice of surgery at Georgetown in 1897 and was active in teaching for thirty-six years. Since 1933, when he became professor of surgery emeritus, he had been a member of the executive faculty and council and administrative advisor to the school. He was past president of the Washington Surgical Society and in 1907-1908 was president of the Association of Military Surgeons of the United States. He was a member of the International Surgical Association, American Surgical Association and the Southern Surgical Association. He was also a founder of the American College of Surgeons and a member of the founders' group of the American Board of Surgery. In 1897 when the Georgetown University Hospital was established, he was appointed chief surgeon. For many years he was surgeon for the Tuberculosis Hospital and consulting surgeon at St. Elizabeth's and Washington Asylum hospitals and the Veterans Bureau, now the Veterans Administration. In October 1944, an oil portrait of Dr. Vaughan was presented to the medical school by members of the medical alumni association; in 1919 he received the degree of Doctor of Laws from Georgetown. Dr. Vaughan was the author of a textbook on "Principles and Practice of Surgery" in 1903 and a volume of "Papers on Surgery and Other Subjects" in 1932.

Guy Hinsdale ⊕ Charlottesville, Va.; born in Brooklyn, Oct. 26, 1858; University of Pennsylvania Department of Medicine, Philadelphia, 1881; member of the West Virginia State Medical Association, American Association for the History of Medicine and the American Neurological Association; served as vice president of the American Academy of Medicine and secretary from 1894-1918, president in 1919 of the American Clinical and Climatological Association, and past president of the Pennsylvania Society for the Prevention of Tuberculosis; member of the English-Speaking Union, American representative of the International Society of Medical Hydrology and fellow of the Royal Society of Medicine, London; in 1937 member of the Congrès International du Tourisme du Thermalisme et du Climatisme; for many years assistant physician at the Orthopedic Hospital and Infirmary for Nervous Diseases and Presbyterian Hospital in Philadelphia; medical director of the Homestead at Hot Springs, Va., from 1904 to 1929, when he was appointed medical director at the Greenbrier at White Sulphur Springs, serving in this capacity until, in 1942, it became the U. S. Army Ashford General Hospital; during World War I was a member of the medical staff named by the Navy to give instructions to newly commissioned officers of that branch of the service; at one time on the faculties of the University of Pennsylvania School of Medicine and the Medico-Chirurgical College of Philadelphia; received the Alvarenga prize from the College of Physicians of Philadelphia in 1895, Boylston prize from Harvard in 1898 and the Hodgkins prize from the Smithsonian Institution in 1914 for his essays on "Syringomyelia," "Acromegaly" and "Atmospheric Air in Relation to Tuberculosis," respectively; author of a book on hydrotherapy; died April 27, aged 89, of paralysis and pneumonia.

Gardner Ellis Robertson ⊕ Captain, U. S. Navy, retired, Yonkers, N. Y.; born Ransomville, N. Y., Feb. 17, 1883; University of Buffalo School of Medicine, 1906; appointed to the medical corps of the U. S. Navy in 1909; was a medical officer on board the *U. S. S. Memphis* when that vessel was beached by a tidal wave near Santo Domingo prior to World War I; commanded the Naval Medical Supply Depot in Brooklyn from 1936 to 1939 and was the senior medical officer of the *U. S. S. Relief* just prior to the outbreak of World War II; in 1941 assigned as medical officer in command of the Naval Hospital at Brooklyn; retired for physical disability on Jan. 1, 1943; following his retirement was retained on active duty in command of the Naval Hospital at Brooklyn until Feb. 1, 1947, when he was placed on inactive status; awarded a letter of commendation, with ribbon, by the Secretary of the Navy for his services in command of the Naval Hospital at Brooklyn during World War II; fellow of the American College of Surgeons; died in St. Petersburg, Fla., March 27, aged 65.

John Auer, St. Louis; born in Rochester, N. Y., March 30, 1875; Johns Hopkins University School of Medicine, Baltimore, 1902; professor and head of the department of pharmacology at St. Louis University School of Medicine; appointed pharmacologist at the Rockefeller Institute for Medical Research in New York, serving until 1921 with the exception of a year as an instructor in physiology, Harvard Medical School, Boston; member of the American Association for the Advancement of Science, the American Physiological Society, Association of American Physicians, Harvey Society and St. Louis Academy of Science; secretary from 1912 to 1916 and president from 1924 to 1927 of the American Society for Pharmacology and Experimental Therapeutics; vice president from 1917 to 1919 of the Society for Experimental Biology and Medicine; major, Medical Officers' Reserve Corps from 1917 to 1922; for many years pharmacologist for St. Mary's group of hospitals; research studies which he conducted included investigations on digestion, respiration, heart, the physiologic action of various drugs, functional disturbances caused by anaphylaxis, war gases, tetanus, reflexes, connective tissues, liver and gallbladder; died in St. Mary's Hospital April 30, aged 73, of rupture of aortic aneurysm.

Richard Sisson Austin ⊕ Cincinnati; born in Providence, R. I., on April 18, 1885; Harvard Medical School, Boston, 1911; Mary M. Emery professor of pathology at the University of Cincinnati College of Medicine; instructor in bacteriology at his alma mater from 1913 to 1915; served as president of the Public Health Federation of Cincinnati, Cincinnati Academy of Medicine and the Ohio Society of Pathologists; vice president of the board of health of Cincinnati; member of the American Association of Pathologists and Bacteriologists and the American Society for Experimental Pathology; director of the pathologic service at Cincinnati General Hospital; consultant at the Children's, Dunham and Hamilton County Home and Chronic Disease hospitals; died in Christian R. Holmes Hospital April 30, aged 63, of carcinoma of the pancreas.

Frederick William Adams ⊕ Carmel, Calif.; born in London, Ontario, Nov. 20, 1880; Western University Faculty of Medicine, London, Ont., Canada, 1906; member of the Washington State Medical Association, American Academy of Ophthalmology and Otolaryngology and the Pacific Coast Oto-Ophthalmological Society; fellow of the American College of Surgeons; past president of the Puget Sound Academy of Ophthalmology; at one time practiced in Seattle, where he was a member of the staffs of the Swedish and King County hospitals and consulting laryngologist at Children's Orthopedic Hospital; oculist, Northern Pacific Railway; died April 1, aged 67, of coronary occlusion.

William Elliott Gamble ⊕ Santa Monica, Calif.; born in Palermo, Ohio, April 9, 1860; Rush Medical College, Chicago, 1886; an Affiliate Fellow of the American Medical Association; member of the Illinois State Medical Society; fellow of the American College of Surgeons; specialist certified by the American Board of Ophthalmology; in 1931 retired from practice in Chicago, where he was professor of ophthalmology emeritus at the University of Illinois College of Medicine, attending ophthalmologist at the University Hospital and a member and past president of the Chicago Ophthalmological Society; died April 23, aged 88, of cerebral hemorrhage.

Bryant Robert Simpson, San Diego, Calif.; born in Venango, Neb., June 24, 1887; University of Nebraska College of Medicine, Omaha, 1910; fellow of the American College of Chest Physicians; member of the American Medical Association, American Trudeau Society and the medical section of the National Tuberculosis Association; past president of the San Diego County Medical Society; served during World War I; formerly attached to the U. S. Public Health Service; during World War II procurement and assignment officer; served on the staff of Mercy Hospital, where he died recently, aged 60, of bronchogenic carcinoma.

Grover Asa Silliman ⊕ Sayville, N. Y.; Baltimore Medical College, 1913; treasurer of the Suffolk County Medical Society; served during World War I; for many years coroner of Suffolk County; from 1919 to 1924 superintendent of the Delaware County Tuberculosis Sanitarium at Delhi, where he was county coroner; medical inspector for the Sayville, Oakdale, Bohemia and Holbrook public schools; affiliated with Southside Hospital, Bay Shore, Central Islip (N. Y.) State Hospital and Mather Memorial hospital, Port Jefferson; died April 27, aged 57, of coronary occlusion.

William Burton Newton, Alpena, Mich.; born in Decatur, Texas, in 1881; Chicago College of Medicine and Surgery, 1911; specialist certified by the American Board of Ophthalmology and the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; for one term president and for three terms secretary of the Alpena County Medical Society; served during World War I; on the staff of Alpena General Hospital; died April 19, aged 67, of coronary disease.

John Clark Arnout, Los Angeles; John A. Creighton Medical College, Omaha, 1907; member of the American Medical Association; on the staff of the Culver City (Calif.) Hospital, where he died March 13, aged 69, of coronary disease.

Morgan Willcox Ayres, Wallingford, Conn.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1875; died in the New York Hospital March 27, aged 96.

David Edwin Baird, Port Orford, Ore.; Baltimore Medical College, 1906; died in McAuley Hospital, Coos Bay, March 30, aged 71, of coronary thrombosis, diabetes mellitus and acute lymphatic leukemia.

Manuel Jay Brown, Salina, Kan.; the Hahnemann Medical College and Hospital, Chicago, 1882; member of the American Medical Association; died March 6, aged 89, of arteriosclerotic heart disease.

Stewart M. Brown, Keechi, Texas (licensed in Texas, under the Act of 1907); died March 2, of cerebral hemorrhage.

Boleslaw Michael Bukowski, Buffalo; University of Buffalo School of Medicine, 1916; member of the American Medical Association; died March 24, aged 54, of coronary thrombosis.

Abner Theodore Clopton, Milan, Tenn.; Vanderbilt University School of Medicine, Nashville, 1902; formerly on the staffs of various Veterans Administration hospitals; served during World War I; died March 18, aged 71.

William Harrison Coffey, Kansas City, Mo.; Missouri Medical College, St. Louis, 1886; member of the American Medical Association; formerly county coroner; served on the staff of Kansas City General and St. Joseph hospitals; died March 25, aged 86, of coronary disease.

R. P. Dickey, Caddo, Okla. (licensed in Oklahoma under the Act of 1908); associated with Wilson N. Jones Hospital in Sherman, Texas, where he died March 20, aged 74, of coronary thrombosis.

John Euclid Fish ⊕ Canton, Mass.; Dartmouth Medical School, Hanover, N. H., 1896; past president of Norfolk District Medical Society; for many years superintendent of the Massachusetts Hospital School; died in Auburndale March 30, aged 75, of myocardial infarction.

Leon Ferdinand Garrigues, New York; University of the City of New York Medical Department, 1891; member of the American Medical Association; died April 4, aged 78, of coronary thrombosis.

Charles Ellis Guthrie ⊕ Seattle; University of Minnesota College of Medicine and Surgery, Minneapolis, 1902; died April 3, aged 79, of carcinoma of the prostate.

William H. Harris, Samoset, Fla.; University of Tennessee Medical Department, Nashville, Tenn., 1888; died March 12, aged 81.

Albert B. Headley ⊕ Cambridge, Ohio; College of Physicians and Surgeons, Baltimore, 1902; past president and secretary of the Guernsey County Medical Society; county health commissioner; surgeon for the Baltimore and Ohio Railroad; died March 5, aged 73, of coronary occlusion.

Judge James, Ackerman, Miss.; Memphis (Tenn.) Hospital Medical College, 1904; member of the American Medical Association; for many years county health officer; died in Grenada, March 22, aged 67, of Adams-Stokes disease.

Ivar Janson, Oceano, Calif.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1892; at one time practiced in Seattle, where he served as president of the board of health; died March 21, aged 79.

I. Warner Jenkins ⊕ Waco, Texas; Chattanooga (Tenn.) Medical College, 1901; specialist certified by the American Board of Radiology, Inc.; member of the American Academy of Dermatology and Syphilology, Radiological Society of North America, Inc., and the American College of Radiology; fellow of the American College of Physicians; member and past president of the McLennan County Medical Society and of the Texas Radiological Society; died March 1, aged 67, of carcinoma of the prostate.

Clay Johnson, Fort Worth, Texas; College of Physicians and Surgeons, Baltimore, 1891; served as president of the city board of education and as a member of the county welfare board; during World War II a member of the county war price and rationing board; a director of the First National Bank; died March 7, aged 81, of hemiplegia.

Frank Goldsmith Lockwood ⊕ Penn's Grove, N. J.; University of Buffalo School of Medicine, 1942; member of the Medical Society of the State of New York; certified by the National Board of Medical Examiners; served with the medical division of the E. I. du Pont de Nemours and Company; died March 9, aged 31, of brain tumor.

John W. Marcy, Merchantville, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1885; died March 8, aged 85, of cerebral thrombosis and arteriosclerosis.

Donald McElderry, Princeton, Iowa; State University of Iowa College of Medicine, Iowa City, 1908; member of the American Medical Association; served during World War I; at one time practiced in Ottumwa, where he was county physician; died in Veterans Administration Hospital, Des Moines, March 15, aged 74.

Horace Victor Pike, Danville, Pa.; University and Bellevue Hospital Medical College, New York, 1899; member of the American Psychiatric Association; for many years clinical director of the Danville State Hospital; from 1938 to 1944 consulting psychiatrist at the Geisinger Memorial Hospital, where he died March 31, aged 71, of acute cholecystitis and congestive heart failure.

William Surber Porter, Oakland, Calif.; University of Pennsylvania Department of Medicine, Philadelphia, 1896; fellow of the American College of Surgeons; served on the staffs of the Samuel Merritt, East Bay, Peralta and Fabiola hospitals; died March 24, aged 80, of heart disease.

Raymond Dustin Potts ⊕ Dayton, Ohio; University of Cincinnati College of Medicine, 1918; on the staffs of the Miami Valley Hospital, St. Elizabeth's Hospital and the Good Samaritan Hospital, where he died March 24, aged 58, of rheumatic heart disease.

Frank Joseph Ronayne ⊕ River Forest, Ill.; Yale University School of Medicine, New Haven, 1904; member of the Radiological Society of North America, Inc.; at one time affiliated with the Veterans Administration Hospital in Maywood; on the staff of the West Suburban Hospital in Oak Park; served during World War I; died in St. Petersburg, Fla., March 24, aged 71, of pneumonia.

Fred Seymour Saruk, Chicago; Chicago Medical School, 1936; member of the American Medical Association; died in the Winfield Hospital March 14, aged 40, of pulmonary tuberculosis.

Benjamin Franklin Scaiefe, Vida, Ore.; St. Louis Medical College, 1887; served during World War I; died March 10, aged 82, of angina pectoris.

Frank Sheehy ⊕ San Francisco; College of Physicians and Surgeons of San Francisco, 1920; fellow of the American College of Surgeons; served on the faculty of his alma mater; on the staffs of St. Francis and St. Joseph's hospitals; died March 13, aged 55, of injuries received in an automobile accident.

William Albert Simpson, Indiana, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1895; member of the American Medical Association; past president of the Indiana County Medical Society; on the staff of Indiana Hospital; member of the board of trustees of the Indiana State Teachers College; served as a member of the board of education; died March 30, aged 76, of coronary embolism.

Amedeo Trappolini, Ashland, Miss.; Middlesex College of Medicine and Surgery, Cambridge, 1922; also a minister; died April 17, aged 59, of injuries received when run over by a truck.

John Henry Von Dreele ⊕ Baltimore; University of Maryland School of Medicine, Baltimore, 1910; affiliated with Maryland General Hospital, where he died March 2, aged 63, of ruptured abdominal aorta.

William Young Ward ⊕ Dodd City, Texas; Medical Department of Tulane University of Louisiana, New Orleans, 1901; died March 25, aged 77, of heart disease.

John Knox Webster, Athens, Texas; Kentucky School of Medicine, Louisville, 1891; member of the American Medical Association; one of the founders and past president of the Henderson County Medical Society; past president of the Eleventh District Medical Society; for four years county health officer; served during World War I; died March 18, aged 81, of pulmonary embolism.

Pulmonary Valvotomy for Congenital Pulmonary Stenosis

Mr. R. C. Brock, Surgeon to Guy's Hospital, has described (*British Medical Journal*, June 12, p. 1121) an advance in cardiac surgery. In 3 cases he performed a direct operation on the pulmonary valves for the relief of pulmonary stenosis. The patients are all alive and their cardiac condition has been improved. A few previous attempts to relieve pulmonary stenosis by operation on the valves have been recorded, but success has been claimed in only 1, recorded by Cutler and Beck in 1929, in which the patient survived four and one-half years and was thought to have been improved. These earlier cases have left the impression that direct surgical attack on the diseased valves is too dangerous to be practicable. Mr. Brock used a special valvulotome for division of the stenosed valve, which enabled the stenosis to be located and divided almost instantaneously. The valvulotome has a gentle curved shaft ending in a blade like a spearhead and carrying a short probe end. A pair of gently curved dilating forceps with fine blades were used after the valvulotome.

In the first case the patient was a girl aged 18, who had been cyanosed from birth. She had great difficulty in getting about and could rarely walk more than 50 yards (45.7 meters). There was a rough systolic murmur, loudest in the pulmonary area, and a faint systolic thrill. After the operation, which was performed on Feb. 16, 1948, she steadily improved. In spite of symptoms on February 24 suggesting arterial occlusion, probably embolic, in the legs, she further improved. On April 10 cyanosis was absent, the finger nails were pink and she walked about the room without dyspnea. It is too early to assess the final result.

The Labeling of Ampules of Anesthetic Drugs

To avoid mistakes the Associations of Anesthetists, British Chemical Manufacturers and the Wholesale Drug Trade have, under the aegis of the Ministry of Health, recommended indelible marking, rather than paper labels, for all ampules containing solids, solutions and solvents which are used for the production of muscular relaxation, spinal, regional or local analgesia and general anesthesia by intratracheal, epidural, intravenous or intramuscular injection or by tissue infiltration. The marking on ampules should be such as will remain legible throughout sterilization of the outside surface and during storage in disinfectant solutions.

The Government and Radioactivity Dangers

A bill to protect workers and the public against the dangers of radioactivity has been introduced by the Government. In moving the second reading in the House of Commons the Minister of Health, Mr. A. Bevan, said that we were now on the verge of vastly extended use of radioactivity. Artificial radioactive substances—radioactive cobalt and radioactive iodine—were becoming available for therapeutic use. They had tremendous dangers and possibilities. In the hands of competent persons there was no danger, but it had been established that the effect of exposure to radioactive substances of high emission was insidious, the consequences over a number of years being possibly fatal. He had been strongly advised by experts that it was necessary to make provision for protection against the possibilities opened up. It was important that Ministers should be given unusual powers, many of which were novel, because of the great difficulty of defining what they were talking about. The gradation from smaller to greater radioactivity was a difference of degree—the difference between a luminous watch and an atomic bomb. Regulations had to be flexible, and to avoid abuse the Government would adopt a new procedure. An advisory committee would be set up, for which the following had been asked to nominate members—the Medical Research Council, the Royal Society, the three Royal Medical Colleges and the Medical Corporations for Scotland, the Faculty of Radiologists, the Department of Scientific and Industrial Research, the British X-Ray and Radium Protection Society, the British Employers Federation and the Trade Union Council. No regulations would be made without this committee's seeing the draft first.

In the discussion it was declared that no other course was open to the Minister than the adoption of such sweeping powers. It was also suggested that there might be a danger at some time of distribution of radioactive material by enemies of the country. Measures should be taken to prevent our reservoirs from being subjected to such attacks. The bill was read a second time.

BUENOS AIRES

New Cardiologic Experiments

Dr. Alfredo Lanari, working in the Institute of Professor Raúl F. Vaccarezza of the Medical Faculty in Buenos Aires, resected circular segments of 1 to 2 cm. of the thoracic aorta of dogs and stitched the ends without interrupting the circulation for more than five minutes (method used by Carrel). For this purpose he employed a glass tube through which the blood circulates while the suture is made. After suturing, one withdraws the tube, removing with special caution the clots which have been formed between the walls of the aorta and the tube. The test animals showed that the interruption of the circulation of the thoracic aorta, with two intercostals tied, originates lesions which are reversible within seventeen to eighteen minutes, but almost never after twenty-two minutes, causing extensive paraplegia.

Furthermore, Lanari and Molins could extirpate fragments of the mitral valve; many of these animals, however, died of embolism. The hemorrhage, on the other hand, could be easily controlled. Three of the surviving animals showed bacterial endocarditis. If dogs operated on in this way are operated on again a year later, great dilatation of the left auricle and hypertension of the pulmonary circuit are found. The maximum murmur of mitral insufficiency, when auscultation was done directly over the heart, was found in the auriculoventricular groove and the left auricle and spread through the pulmonary veins. Intense murmurs were not heard at the apex of the heart; therefore the valvular origin of the systolic murmur heard in the region of the apex of certain persons seems to be problematic.

Lanari and Sampietro made in dogs a venovenostomy between a pulmonary vein and the vena azygos major, in order to alleviate the congested pulmonary circulation in mitral stenosis and insufficiency. Through the procedure a venovenous fistula is made. The operation is simple, but thrombosis is frequent.

International Congress on Echinococcosis

This congress was held in Azul (Province of Buenos Aires) with the assistance of representatives of Brazil, Chile, Panama, Paraguay, Uruguay, Venezuela and specially invited guests of other Latin-American countries, as well as from Italy, Netherlands and Spain. The minister of public health of the province stated that Argentina has a high degree of Echinococcus infections which has considerably increased since 1935; 10 to 15 per cent of the persons operated on for cysts died. A similar situation exists in Uruguay, and the infection is commencing in Brazil and Chile.

In his lecture on "Pathology of the Hydatid Cysts of the Lung" Dr. Velarde Pérez Fontana (Uruguay) referred to the new concept of the pathology of the cyst on which a new surgical procedure has been developed: the extirpation of the adventitious membrane which forms around the cyst. The surgical technic was discussed by Professor Iván Goñi Moreno (Buenos Aires). Only exceptionally should other methods be employed. According to further discussions the method employed in the Institute of Thoracic Surgery in Montevideo (Prof. Ugón) for enucleation of hydatid cyst of the lung consists in making an incision of the adventitia and then using the finger for opening a space so as to draw out the cyst without breaking it. According to the method of Posadas, the cyst is evacuated entirely or with the aspirator of Finochietto, and the bronchi which end in the cavity are closed.

The biologic method of Calcagno (Buenos Aires) consists in injecting hydatid antigen (made from the hydatid liquid and the triturated membranes), which alleviates the symptoms and frequently cures the disease. If the operation is indicated, the previous biologic treatment is all the more desirable. Dr. Pérez Fontana, however, insisted that this biologic method is indicated and satisfactory only when the cyst is broken, while in other cases the surgical method is superior.

GERMANY

(From Our Regular Correspondent)

June 24, 1948.

News from Mainz University

Among the German universities, the University of Mainz has assumed a special role. It is the only university founded by the Occupation Authority (French), and it has been assigned the task of fostering cooperation and fellowship among students from Germany and all other countries. It has introduced the American type of campus life, boarding and housing, a novel feature in German university life.

The university has been largely assisted by the relief program of the Mennonite communities of the United States and Canada, which have organized a student feeding program. About 2,000 students have been receiving two weekly meals of 600 calories, and the program will be enlarged to take in more students.

The university has received a Y.M.C.A. student library consisting mostly of Anglo-American literature. The administration of the library is in the hands of a displaced persons' student union which has been organized at that university.

Dr. Podach, co-worker of the Institute for Medical History of Mainz University, has published a timely article: "The Mortality from Childbed Fever and the Revolution of 1848." He points out: 1848 is known as the year of the German liberal revolution. In medicine, it is also known as the year of the first successes in the fight against childbed fever, after the discovery by Semmelweis that students who carried germs directly from necropsies to the delivery room were mainly responsible for the terrifying Vienna statistics of that time. Chemical and mechanical prophylaxis was introduced and statistics showed a striking improvement immediately thereafter, in 1848. Dr. Podach undertakes to attack the interpretation by Semmelweis of these two facts as cause and consequence, by pointing out that the real reason for this apparent success was more political than medical. Semmelweis himself participated too actively in the revolution to be able to devote much time to clinical work (he gave no obstetrical courses at that time). The students were too busy attending political meetings and fighting on the barricades to work either in pathologic or obstetric departments. Dr. Podach is of the opinion that these facts were more responsible for the excellent statistics of 1848 than the immediate effects of Semmelweis' discovery.

Synthetic Fats for Human Consumption

The production of fats from German-fed animal sources amounted to only 50 per cent of the total requirements of fats for Germany in 1938. To cover the deficit, fat and/or fodder had to be imported. This accounts for the lack of fats in present day Germany. Lately, the daily press has frequently discussed the use of synthetic fats for human consumption. Professional journals too have taken up the issue, the authors drawing different conclusions from their findings.

Prof. Dr. Karl Thomas and Dr. Guenther Weitzel, Leipzig, report in the *Deutsche Medizinische Wochenschrift* about the fitness for human consumption of synthetic fats produced from coal. In the American-licensed *Sueddeutsche Apothekerzeitung* there is a report on the same problem by Dr. Gustav Geist. Dr. A. Krautwald, acting director of the 2nd Medical University Clinic of Berlin, gives a thorough account on the problem in the June 15, 1948 issue of *Das Deutsche Gesundheitswesen*, the official organ of the Health Administration in the Soviet Zone—incidentally the last number which has come through to the American Zone from Berlin since the beginning of the Soviet blockade. Thomas and Weizel report that tests with respect to the tolerability of synthetic fats have shown that an amount of 100 Gm. per day, given for a week, was consumed without any harmful effects, while the consumption of 150 Gm. daily was followed by different disturbances. While natural fats are almost completely metabolized into carbon dioxide and water, synthetic fats leave large amounts of acid waste products, as was proved by urinalyses. Geist, arriving at almost identical chemical results, stresses that consumption over a longer period of time may lead to disturbances, particularly in the kidneys, and also to decalcification of the bones. He concludes that thorough biologic tests will be necessary before synthetic fats are to be released for human consumption. In contrast to this, Krautwald's conclusions read as follows: "The fat examined proved to be highly fit for any dishes requiring fats, and for a paste. Persons in good health could very well digest doses of 100 Gm. per day. The tasty fat causing no detrimental effects or disturbances of health was digested without any trouble even by persons with liver or stomach complaints in quantities up to 50 Gm. per day." In his opinion, it is "urgently necessary to resume the production of synthetic fat and to continue research in that field."

Miscellaneous

A survey about the nutritional situation in the American Sector of Berlin, published in February, showed that a considerable part of the Berlin population is suffering from undernourishment. Qualitatively, the lack of proteins constitutes the most serious problem, while lack of vitamins as such has not led to serious consequences. This is probably due to the fact that, with a low metabolism, the need for vitamins is also lowered.

The *Deutsche Medizinische Rundschau* publishes a report on the tragic situation in Luebeck. There are 90,000 evacuees in that city, and infant mortality has risen to 25 per cent. There are no diapers available, and even the formerly used substitutes, like old maps, pasted on linen, or British food bags, have been used up. Now, old newspapers are used for diapers. The correspondent stresses that such conditions lead not only to an increased infant mortality rate, but also to many maternal deaths owing to increased abortions.

Giessen, the only university in Germany which lacks a medical faculty, will now open an Academy for Medical Research and Training. Part of it will be the former Kaiser Wilhelm Institute for Brain Research, which is now located in Dillenburg, Hesse, and which will be moved to Giessen this year.

At Cologne University, a student group of conscientious objectors was founded. It appeals not only to students opposed to war for moral and religious reasons, but also to those who are "against this scourge of humanity from a purely practical standpoint." Similar students' groups exist in twenty-four different countries, and they are organized in the "International of Objectors to Military Service."

Bureau of Investigation

HOXSEY IN MEXICO

From a Mexican newspaper dated April 12, 1948, comes an item which is translated as follows:

"Like soldiers in their trenches, a veritable army of scientists have begun from their laboratories and experimental clinics a bloody and brave battle against cancer That fight for humanity under the flag of health has been struggling for liberation for many decades.

"Three soldiers of that army which is combating one of the most tremendous scourges of the human race are in Monterrey living at the Hotel Bermuda they are Dr Harry M Hoxsey, Director of the Hoxsey Cancer Clinic in Dallas, Texas, Dr C. E Von Hoover of San Antonio, Texas, chemist in the same institution, and the opulent landowner Mr J Thomas Hopkins of Longview, Texas, who has been contributing to the work of the great anti-cancer crusade.

Three Generations of Doctors Hoxsey

"During the last decades of the past century, Drs John Hoxsey Sr and John Hoxsey Jr., father and grandfather respectfully of Dr. H. M Hoxsey, have been applying a natural system in treating cancer, which, according to comments of the third of that dynasty of physicians, has nothing to do with surgery or use of radium . . ."

The Hoxsey family genealogy was noted first in THE JOURNAL of Jan. 2, 1926 The ebullient son was considered in an editorial in the March 15, 1947, issue of THE JOURNAL.

Accompanying this Mexican newspaper article were copies of two letters sent by Hoxsey in support of his treatment They are signed by "C. E Von Hoover, Ph D, Consulting Chemist-Pharmacologist." One, dated Dec 11, 1947, to the Hoxsey Cancer Clinic, Dallas, Texas, is entitled "Tests Hoxsey Cancer (Internal) Treatment." The chemist has found, as the essentials of such treatment, the following

"This preparation contains and is found in the analysis—a most vf special type of scientifically and specially prepared Iodine, as well as in the same perfected manner is found Osmunda regalis facto (alkaloid free), which creates by mixing the above two ingredients, V. Conservatrix and Conium lx, the first and later are indicated for the treatment of carcinoma and cancerous tumors by the Homeopathic Materia Medica (Ref Luyties M M Page 150 Carcinoma). This is created and formed because the preparation contains no metals, therefore, it is—in my opinion a valuable chemotherapeutic

"Among other elements noticed in this preparation are traces of colloidal gold The preparation is COLLOIDAL, a-gold mixture creating another element therapeutic agent"

The next sentence is rather staggering It constitutes a broad indictment of the medical profession and its abilities when it comes to the matter of the mixing of drugs

"The outstanding results obtained in the treatment of carcinoma by physicians who prescribe same are no doubt due to the great therapeutic value produced by the mixture of the special ingredients and the secret process of mixture; since this preparation is mixed by a physician, therefore, we are not in position as to find by study and analysis the method used"

The copy of the second letter is dated Dec 14, 1947, and says:

"Research reveals that the outstanding therapeutic values you receive in the treatment of all types of carcinoma, in addition to other reports submitted you by the writer, is due to the fact that the 'crossing' of the drug ingredients contained in Hoxsey treatment, produces because of same, by reason of: a reaction chain which the fluorescent substances serve as a group of reactants, producing the carrier and producing by-product values. The by-products are 'end' products, are produced by the ingredient mixtures contained in the preparation, thereby creating a virus destroying agent, in this way Calcaria Fluorica of homeopathy proved useful in cancer

"Physicians using this preparation should bear in mind that sometimes we of the scientific 'galleys' can not explain in a professional or any other language why simple mixture of simple drugs produce startling therapeutic values; when they do and are safe in administration, results are all that is necessary.

"You, Dr. Durkee, are the best reference that the preparation has, for the reasons that under your direction you have witnessed the results, in my opinion, the results are due to my above and other explanation in my reports to you.

"I have spent much time in analysis, research and works of almost every nature with this product. It becomes interesting at all times, the more you look into same, the more interesting matters come to light"

The second letter was addressed to Dr. J. B. Durkee, the medical director of the Hoxsey Cancer Clinic, an osteopath An article of his appeared in a recent issue of the *Journal of the National Medical Society.* The article is prefaced by an editor's note which says of the use of the Hoxsey treatment that the American Medical Association "had their chance and they arrogantly and stupidly rejected it."

Well! An editor is known by the articles he publishes!

Medical Motion Pictures

FILM REVIEWS

The Role of Gastroscopy in the Diagnosis and Treatment of Gastric Pathology. 16 mm., color, sound, 1,200 feet (one reel), showing time thirty-three minutes. Prepared by Leo L. Hardt, M.D., Department of Medicine, Loyola University School of Medicine, Chicago. Produced in 1947 by Jam Handy Organization, Chicago. Procurable on loan from Harrower Laboratory, 5 South Wabash Avenue, Chicago.

This film presents gastroscopy and its place in the diagnosis of gastric disease in an informative manner Following a brief historical introduction, it shows the development of the modern flexible gastroscope The indications and contraindications for gastroscopy are clearly defined and evaluated. By appropriate models, roentgenograms and other illustrative material the film clearly depicts the lesions which may be differentiated by gastroscopy. Notable is the emphasis given to close cooperation between the gastroscopist and roentgenologist in diagnosis of gastric lesions Clearly shown are the advantages and disadvantages of each diagnostic procedure, and emphasis is made on the proper integration of these diagnostic aids.

The last part of the film deals with the evaluation of various gastric antacids by gastroscopy. This is perhaps the least educational portion of the film, since there appears to be some bias in favor of a particular mixture However, the technic of evaluation is interesting and instructive. The film appears suitable for teaching medical students and for presentation to a general medical audience. The photography is excellent, but the narration is poor

Substitution Transfusion In The Treatment Of Erythroblastosis Fetalis. 16 mm., color, silent, 800 feet (one real), showing time thirty minutes. Prepared in 1947 by and procurable on loan from Harry Wallerstein, M.D., Director, Erythroblastosis Fetalis Clinic, Jewish Memorial Hospital, and the Department of Hematology, Morrisania City Hospital and Queens General Hospital, New York.

The film presents substitution transfusion in the treatment of erythroblastosis fetalis. The three technics used for the removal of the infant's blood are shown, namely, the longitudinal sinus, the umbilical vein and the radial artery. Each procedure is depicted in detail; this will aid the surgeon greatly in learning the methods. The criteria for selection of cases are given. The author seems rather confident that the operation will prevent development of kernicterus. Calcium gluconate is administered to counteract the large amounts of sodium citrate. Would it not be advisable to give it in divided doses instead of only at the completion of the procedure? Obstetricians and pediatricians may object to too much exposure of the baby during the fairly long procedure. The surgeon will wonder why a local anesthetic was not used for the venesection. Many would like to know how long each operation takes in an average case.

The author used excellent judgment in the choice of material in his emphasis on particulars and in selection and formulation of descriptive matter. This film can be recommended to all those interested in the treatment of erythroblastosis fetalis. The mortality rate as given in the final statistical summary understates the true mortality among the treated infants; the rate of 2 per cent was computed from the total of 62 treated and untreated infants, yet the rate is referred to as being based on infants treated according to plan.

MEDICAL MOTION PICTURE REVIEW

First Steps. 16 mm., black and white, sound, 375 feet, showing time ten minutes Prepared under the supervision of the Department of Public Information of the United Nations with medical supervision by N. Purshotton, M.D., India Produced in 1947 by Frederic House, New York. Procurable on rental from. Film Program Services, 1173 Avenue of the Americas, New York 19.

This is a documentary film on the rehabilitation of children afflicted with poliomyelitis and cerebral palsy. Taken in a rehabilitation camp for the orthopedically handicapped child, an excellent series of sequences shows the methods of training disabled children to walk again and to become useful citizens. The film stresses the concept that "since the child himself is developed, as well as his legs, walking is a beginning and not an end."

This film was originally planned to be used primarily for child welfare work in India; thus the term "social worker" is used throughout, whereas the Western World would more correctly use the words "physical therapist."

The film has dramatic appeal, and the filming and sound track are superlative; it will interest physicians, physical therapists, occupational therapists, social workers, lay groups who are concerned with the welfare of the crippled child and parents of handicapped children.

PUBLIC HEALTH SERVICE FILMS

The following 35 mm., sound, black and white film strips with records have recently been released by the United States Public Health Service, Communicable Disease Center, Atlanta 3.

Laboratory Diagnosis of Rabies emphasizes that laboratory diagnosis of rabies depends on the ability of the laboratory technicians to determine the presence or absence of Negri bodies. Photographs of the Negri bodies will accompany the film strip. (Running time eight minutes.)

The Fight Against Rabies is intended to eliminate rabies through close cooperation of citizens with local, state and federal authorities engaged in a national eradication program. (Running time fourteen minutes.)

Spread and Prevention of Trichinosis discusses symptoms, life cycle of Trichinella Spiralis, statistical analysis in relation to incidence of the disease and means of prevention. Suitable for showing to subtechnical audiences and is related to the film strip entitled "Worms in Your Muscles." (Running time twelve minutes.)

Worms in Your Muscles depicts the life cycle of the Trichinae, the symptoms and prevention of the disease. Suitable for showing to technical audiences and is related to the film strip entitled "Spread and Prevention of Trichinosis." (Running time ten minutes.)

These film strips are procurable on a short term loan (thirty days) through the following address: Medical Director in Charge, Communicable Disease Center, 605 Volunteer Building, Atlanta 3, Ga., Attn: Film Library.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and the Examining Boards in Specialties were published in The Journal, July 17, page 1081.

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 28-30, 1949. Sec., Dr. D. G. Gill, 519 Dexter Ave., Montgomery.

Alaska: * *Examination.* Juneau, Sept. 7. Sec., Dr. W. M. Whitehead, Box 140, Juneau.

California: *Oral.* Los Angeles, Aug. 7-8. *Written.* Los Angeles, Aug. 9-12; Sacramento, Oct. 18-21. Sec., Dr. Frederick N. Scatena, 1020 N. Street, Sacramento 14.

Connecticut: * *Examination.* Hartford, Nov. 9-10 Sec., Dr. Creighton Barker, 258 Church St., New Haven.

District of Columbia: * *Reciprocity.* Washington, Sept. 13. Sec., Commission on Licensure, Dr. G. C. Ruhland, 4130 Municipal Bldg., Washington, D. C.

Georgia. *Examination.* Atlanta, Oct. 12-13. *Endorsement.* Atlanta, Oct. 14. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta.

Illinois: Chicago, Oct. 5-7. Supt., Dept. of Registration and Education, Mr. Fred W. Ruegg, Capitol Bldg., Springfield.

Iowa: * *Examination.* Des Moines, Dec. 6-8. *Endorsement.* Des Moines, Aug. 2. Sec., Dr. M. A. Royal, 506 Fleming Bldg., Des Moines.

Maine: Portland, Nov. 9-10. Sec., Board of Registration of Medicine, Dr. Adam P Leighton, 192 State St., Portland.

Maryland: *Examination.* Baltimore, Dec. 14-17. *Endorsement.* At the discretion of the Board. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore.

Minnesota: Minneapolis, Oct. 19-21. Sec., Dr. J. F. DuBois, 230 Lowry Medical Arts Bldg., St. Paul 2.

Missouri: Jefferson City, Aug. 8. Exec. Sec., Mr. J. A. Hailey, Room 135 Capitol Bldg., Jefferson City.

Montana: Helena, Oct. 4-6. Sec., Dr. O. G. Klein, First Nat'l Bank Bldg., Helena.

Nevada: Carson City, Nov. 1. Sec., Dr. G. H. Ross, Industrial Bldg., Carson City.

New Hampshire: Concord, Sept. 9. Sec., Board of Registration in Medicine, Dr. J. S. Wheeler, Room 107, State House, Concord.

New Mexico: * Santa Fe, Oct. 11-12. Sec., Dr. V. E. Berchtold, 141 Palace Ave., Santa Fe.

New York: *Examination.* Various Centers, Sept. 27-30. Sec., Dr. J. I. Lochner, Jr., 23 South Pearl St., Albany 7.

Ohio. *Examination.* Columbus, Dec. *Endorsement.* Columbus, Aug. 9, Oct. 5. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

Pennsylvania: *Examination.* Philadelphia, Jan., 1949. Act. Sec., Mrs. M. G. Steiner, 351 Education Bldg., Harrisburg.

Rhode Island. * *Examination.* Providence, Oct. 7-8. Chief, Div. of Professional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence

South Carolina. *Endorsement* Aug. 2, Sept. 6. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

West Virginia Charleston, Oct. 4-6. Sec. Public Health Council, Dr. N. H. Dyer, State Dept. of Health, Charleston

Wisconsin * Madison, Jan. 11-13, 1949 Sec., Dr. C. A. Dawson, Tremont Bldg., River Falls, Wis.

Wyoming: *Examination.* Cheyenne, Oct. 4. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

---

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Alaska: Juneau. Last week in Aug. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau

Arizona: *Examination.* Tucson, Sept. 21. Sec., Mr. Francis A. Roy, Univ. of Arizona, Tucson.

Colorado *Examination.* Denver, Sept. 15-16. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver 3.

District of Columbia. *Examination.* Washington, Oct. 18-19. Sec., Dr. G C. Ruhland, 4130 Municipal Bldg., Washington, D. C.

Florida: *Examination.* Gainesville, Nov. 6. Final date for filing application is Oct. 25. Mr. M. W. Emmel, University of Florida, Gainesville.

Iowa. Des Moines, July 13, Oct. 12. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

Michigan: *Examination.* Ann Arbor and Detroit, Oct. 8-9. Sec., Miss Eloise LeBeau, 1510 West Allegan St., Lansing.

Minnesota: *Examination.* Oct. 5-6. Sec.-Treas., Dr. Raymond N. Bieter, 105 Millard Hall, Univ. of Minnesota, Minneapolis.

Nebraska: *Examination.* Omaha, Oct. 5-6. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, Room 1009 State Capitol Bldg., Lincoln.

New Mexico: *Examination* Santa Fe, Aug. 1. Sec., Miss Marguerite Kilkenny, P. O. Box 307, Santa Fe.

Oklahoma: Spring of 1949. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Oregon: *Examination.* Portland, Sept. 4. Sec., Basic Science Examining Committee, Dr. C. D. Byrne, Univ. of Oregon, Eugene.

Rhode Island: *Examination.* Providence, Aug. 11. Chief, Div. of Professional Regulation, Mr. Thomas B Casey, 366 State Office Bldg., Providence.

South Dakota. *Examination.* Vermillion, Dec. 3-4. Sec., Dr. G. M. Evans, Yankton.

Tennessee. *Examination.* Memphis & Nashville, Sept. 20-21. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis.

Wisconsin: *Examination.* Madison, Sept. 25. Final date for filing application is Sept. 15. Sec., Prof. W. H. Barber, Scott & Watson Sts., Ripon.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Nurses: Right of Physician to Procure Dismissal from Case.—The plaintiff filed a suit for damages against the defendant physician for having "procured" the hospital authorities to dismiss her from a case and to prohibit her from being called as a special nurse at the hospital. The jury found for the plaintiff, but the trial court entered a verdict for the defendant. The plaintiff, therefore, appealed to the Supreme Judicial Court of Massachusetts.

The plaintiff testified that in 1936, while doing special nursing in the hospital, her patient was annoyed by a patient of the defendant continuously ringing the bell. The plaintiff asked the defendant's patient to give short rings instead. The next day the defendant demanded that the plaintiff apologize to his patient, which the plaintiff did. On that occasion the defendant said, "I will get you off . . . registry if it is the last thing I do." He was "very very mad." He told the plaintiff to have "nothing to say or do" to him or his patients, so from that time on the plaintiff and the defendant never spoke to each other. On Oct. 21, 1941, the plaintiff was caring for a patient at the hospital and a patient of the defendant was in the same room. One evening, after visiting hours were over, the plaintiff, desiring to give some needed attention to her patient, requested another nurse to remind some persons then visiting the defendant's patient that it was after visiting hours. The defendant's patient became excited about this. Two days later the superintendent of the hospital (who had direct charge of the care of patients and of nurses and had jurisdiction over the plaintiff) called the plaintiff on the telephone and said, "I am omitting you from your case . . . . Dr. Williams wants to talk with you." The defendant, then taking the telephone, "yelled" at the plaintiff, "Why did you tell my patient I was only worth two cents?" The plaintiff denied having told that to the patient. The defendant said, "And why did you tell my patient's visitors to leave?" After more words, the defendant said, "I have told . . . [the superintendent] that you are never to work in this hospital again and that if you come back here to work I will never send another patient here. I have told her it is either you or me. There is not room enough here for both of us." The plaintiff said, "Dr. Williams, you have no right to talk to me like that, or have me taken off the registry." He replied, "It isn't a matter of what I have a right to do, it is what I have done." Later the superintendent said to the plaintiff that the defendant was a very important man in the hospital, that he had said that if the plaintiff were put back on the list he would never send another patient to the hospital, that the superintendent was not a free agent in the matter and that the plaintiff could not go back on the list until she had seen the defendant and fixed it up with him and placated him. The plaintiff said she could not do that. No witness testified that the plaintiff in fact did make the derogatory remarks mentioned, and she testified in effect that she did not.

The defendant's position, supported by his testimony, was, in substance, that he was conscious of no ill will against the plaintiff until she brought this action, that he simply reported to the superintendent what his patient had told him as to the conduct and language of the plaintiff, which in his opinion were a breach of ethics, that he did not request the superintendent to omit the plaintiff or to take her name off the list and that the superintendent acted on her own initiative. He denied having made most of the statements attributed to him by the plaintiff.

The only question, said the court, was whether or not the evidence warranted a verdict for the plaintiff. If the jury believed the evidence most favorable to the plaintiff, they could find that having her name on the hospital's list of nurses and the privilege of nursing at the hospital were business relationships valuable to the plaintiff in that they afforded her a fairly reasonable means of access to employment in her profession. They could find that these valuable relationships would have continued, if it had not been for the persuasion and influence of the defendant. They could find that in 1936 the defendant threatened to get the plaintiff off the registry of the hospital and that in 1941 he practically commanded the superintendent to dismiss the plaintiff on the threat to bring no more patients to the hospital if she did not do so and that the superintendent acted as she did in consequence of that threat. They could find that the defendant's conduct was purposely directed toward securing the dismissal of the plaintiff from the hospital, with full knowledge of the consequences to her, and that it was successful in bringing about that result.

The governing principle of law, said the Supreme Court, is set forth in Restatement, Torts, Section 766, in these words, ". . . one who, without a privilege to do so, induces or otherwise purposely causes a third person not to . . . enter into or continue a business relation with another is liable to the other for the harm caused thereby." Our own decisions, the court continued, appear to be in accord with this statement, and in order to maintain the action it is not necessary that the plaintiff prove that she had a binding contract with the hospital. It is well settled that an existing or even a probable future business relationship from which there is a reasonable expectancy of financial benefit is enough. The next inquiry is therefore whether a privileged occasion existed on which the defendant could rely as justification for knowingly and intentionally causing damage to the plaintiff. We assume, said the court, that if the plaintiff did disparage the defendant to his own patient a privileged occasion would arise which would justify the defendant in doing something in relation to the matter for the purpose of maintaining necessary discipline in the hospital and efficient working relations between nurses and physicians. A privileged occasion of some sort might perhaps arise if the defendant had been credibly informed and believed that the plaintiff had made the statements attributed to her, even if in fact she had not made them. We do not decide these questions. The difficulty with the defense is that the plaintiff did not admit either having made the statements or that the defendant had been informed that she had made them. Although no witness testified to the actual making of the statements, there was much evidence that the defendant had been informed that they were made. But none of this evidence bound the plaintiff. The jury could have disbelieved *in toto* the evidence tending to show a privileged occasion. Since the jury were not obliged to believe that any privileged occasion existed, they could have found for the plaintiff on the ground that the defendant's injury to the plaintiff remained wholly unjustified. The conclusion is unescapable, said the Supreme Court, that this was a jury case. Accordingly the verdict of the trial court, which was contrary to the jury's finding, was set aside and the verdict of the jury reinstated. *Owen v. Williams, 77 N.E. (2d) 318 (Mass., 1948).*

Charitable Hospitals: Liability for Injuries to Patient Falling Out of Bed.—The plaintiff sued for damages for injuries sustained while a patient in the defendant hospital. From a judgment for the plaintiff the defendant appealed to the supreme court, appellate division, third department.

The plaintiff, an infant slightly over 2 years of age, had a generalized eczema over his head and body, with swollen glands in his neck and behind his ears. He was running a temperature of more than 103 F. when taken to the defendant hospital, as a paying patient, and placed in a crib, the top of which was 57¼ inches from the floor and 25 inches from the upper side of the mattress. Three days later the child climbed over the side of the crib and fell to the floor, receiving the injuries forming the basis for this suit.

Pointing up the question of the liability of a charitable hospital, the court quoted a prior New York case as follows: "Certain principles of law governing the rights and duties of hospitals, when maintained as charitable institutions, have, after much discussion, become no longer doubtful. It is the settled rule that such a hospital is not liable for the negligence of its physicians and nurses in the treatment of patients. . . . This exemption has been placed upon two grounds. . . . The second ground of the exemption is the relation subsisting between a hospital and the physicians who serve it. It is said that this relation is not one of master and servant, but that the physician occupies the position, so to speak, of an independent contractor, following a separate calling, liable, of course, for his own wrongs to the patient whom he undertakes to serve, but involving the hospital in no liability, if due care has been taken in his selection. . . . It is true, I think, of nurses, as of physicians, that, in treating a patient, they are not acting as the servants of the hospital. The superintendent is a servant of the hospital; the assistant superintendent, the orderlies, and the other members of the administrative staff are servants of the hospital. But nurses are employed to carry out the orders of the physicians, to whose authority they are subject. The hospital undertakes to procure for the patient the services of a nurse. It does not undertake, through the agency of nurses, to render those services itself."

Applying these principles to the facts of the present case, the court was of the opinion that the evidence did not warrant the finding that a professional determination had been made by the receiving nurse or any other nurse or physician that additional restraint was necessary, thus making the failure to apply such paraphernalia an administrative act for which the defendant was chargeable. Accordingly the judgment in favor of the plaintiff was reversed. *Pierson v. Charles M. Wilson Memorial Hospital, 78 N. Y. S. (2d) 146 (N. Y., 1948).*

Naturopathy as Practice of Medicne.—The defendant was convicted of unlawfully practicing medicine and surgery without a license so he appealed to the Court of Appeals of Ohio, Franklin County.

A witness for the prosecution testified that she went to the defendant's office suffering from a pain in her leg and was first examined by a Mr. Good in the defendant's office, after which she was in consultation with both the defendant and Mr. Good. The defendant told her that her glands did not function properly, prescribed thyroid tablets, a box of capsules and several other different kinds of medicine and injected oxygen into her leg by means of a hypodermic needle. She said that the defendant prescribed the medicine for her and that she paid him $10 for the examination and that the medicine was $16. The defendant admitted giving her the oxygen treatment and also admitted that all of the office equipment belonged to him and that all money received from patients was turned over to him. It was also admitted that the defendant was not licensed by the State of Ohio.

The statutes of Ohio provide: "A person shall be regarded as practicing medicine, surgery or midwifery, within the meaning of this chapter . . . who examines or diagnoses for a fee or compensation of any kind or prescribes, advises, recommends, administers or dispenses for a fee or compensation of any kind, direct or indirect, a drug or medicine, appliance, application, operation or treatment of whatever nature for the cure or relief of a wound, fracture or bodily injury, infirmity or disease. . . ."

The defendant contended that he was practicing naturopathy and that naturopathy is not medicine or any of its branches within the purview of the above quoted statute. We are not interested in what name or title the defendant gives to his profession, said the court of appeals, but we are only interested in whether or not what he did constituted the practicing of medicine as defined by the statute. There is testimony in the record to the effect that he examined, prescribed and dispensed for a fee certain medicines and that he gave a treatment by means of the oxygen needle. The defendant contended that what he gave to Mrs. Linn was neither a drug nor a medicine. Winston's Universal Reference Library, said the court, defines medicine as being "any drug or remedy for the treatment and cure of disease." Medicine, therefore, is not only a drug but is also a remedy. The statute may be violated by the dispensing of a remedy as well as a drug. On one of the state's exhibits received by the witness at the defendant's office, we find the warning: "To be used only by or on the advice of a doctor." On another we find: "Active ingredient thyroid. To be used only by or on the prescription of a physician. It is not safe to take thyroid except under the supervision of a physician." We are therefore of the opinion, the court concluded, that there was ample evidence in the record to support the verdict of the jury and it is not against the manifest weight of the evidence. Accordingly, the judgment of conviction was affirmed.—*State v. Henning, 78 N. E. (2d) 588 (Ohio, 1948).*

Employers Duty to Notify Employee of Results of Physical Examination by Company Doctor.—The plaintiff sued his employer and a fellow employee for damages sustained, as a result of an injury during the course of his employment, by reason of the negligence of the fellow employee. From a judgment for the plaintiff, the defendants appealed to the Supreme Court of Oklahoma.

The evidence showed that, in April 1942, one of the toes of the plaintiff's left foot became infected. Subsequent hospitalization at the railroad hospital revealed that the plaintiff was afflicted with Buerger's disease (thromboangiitis obliterans), a disease which causes the blood vessels in the extremities to be obstructed. When blood cannot reach the toes or other afflicted parts, gangrene sets in and amputations become necessary to prevent further spread of the disease. The plaintiff received treatment for his left foot until July, when his left great toe was amputated. He returned to work in January 1943, as a section hand, and continued in such employment until April. At some time during that period he was lifting a tie with a fellow employee. His co-worker jerked or dropped the tie, causing the plaintiff to fall into a trench and strike his right ankle on a big cinder. He was given treatment for the resulting infection in his right ankle from April to August, when he went to the company hospital again and, in December, underwent amputation of his right leg. The infection and subsequent amputation of the right leg was due to the fact that he was afflicted with Buerger's disease. The plaintiff's evidence indicated that he at no time knew or was told that he had Buerger's disease and at no time was warned of any dangers or unusual perils which might befall him because of this affliction. He contended, however, that the employer knew that he was so afflicted and that it was therefore negligent in permitting him to return to work as a section hand when it knew that it was hazardous to employ him at work in which he might receive a blow or bruise which might, or probably would, cause an aggravation of the disease, resulting in a gangrenous condition and possible amputation of the afflicted portion of the plaintiff's body. The plaintiff also contended that the employer was negligent in failing to inform him of his condition.

The employer's principal contention was that the duty rests on the servant to determine for himself whether or not he has sufficient health and strength to perform the duties of a position and not on the master. This rule, said the Supreme Court, is based on knowledge or presumed knowledge on the part of the servant and is inapplicable to the case at bar. The right to recovery in this case is based on positive lack of knowledge by the servant of his affliction and therefore lack of knowledge of exposure to greater dangers than the work necessarily entailed.

The employer also contended that the instructions were erroneous, in that they failed to place on the plaintiff the burden of proving that the defendant employer knew that the plaintiff was ignorant of having the disease and the probable effect thereof. According to the undisputed evidence, the court said, the plaintiff was afflicted with a rare disease not commonly known or recognized, difficult of diagnosis and discovery and unusual in its nature; the plaintiff received no treatment at any time except from the defendant company physician or physicians in communication with the defendant company. The instructions given placed the burden on the plaintiff of proving not only that the physicians discovered the disease but that they did not at any time tell him of his condition or the nature and characteristics of the affliction and that he did not receive such knowledge from any source. According to the undisputed facts in this case, the court concluded, the instruction given in effect required the plaintiff to establish that the employer knew him to be ignorant of his condition, and the jury resolved this question in favor of the plaintiff.

In conclusion, the Supreme Court held that the instructions correctly stated the issues presented by the pleadings and the evidence and correctly stated the law applicable thereto and, further, that there was competent evidence reasonably tending to support the verdict of the jury. The judgment in favor of the plaintiff was accordingly affirmed. *Atchison, T. & S.F. Ry. Co. v. Perryman, 192 P. (2d) 670 (Okla., 1948).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Effect of Occlusive Diseases on Blood Supply of Nerves.—According to Roberts and associates the blood supply of peripheral nerves has received little attention in connection with clinical problems since it is common belief that the metabolism of a peripheral nerve depends on the cell bodies of its neurones rather than on the nourishment of its axones. The author's studies indicated that ischemic nerves suffered changes in function and structure. Experiments consisted of interference with the blood supply of peripheral nerves in various ways. Clinical cases were collected where the influence of ischemia on a peripheral nerve could be demonstrated by dissection and injection. The blood supply of nerves has been shown to be abundant. This blood supply was obliterated by ligating nutrient arteries of a nerve, by stripping off the epineurium, by compressing a nerve or stretching it and by injecting embolic substances into a nutrient artery. Having produced ischemia of the nerve by these methods, it was studied by injecting dye through the aorta into the vasa nervorum and was found to alter the function and structure of the nerve. Peripheral nerves of man may be made ischemic by similar processes and by proliferative, vasospastic or thromboembolic vascular diseases affecting either arterial or venous blood supply of the nerves in a great variety of clinical conditions (for example, diabetes mellitus, thromboangiitis obliterans, arteriosclerosis, arterial embolism and thrombosis, phlebothrombosis, stretching or compression of nerves, anemia or hemoconcentration). Sensory and motor changes were closely correlated with ischemia of nerves in the cases studied by injecting dye or by sections. Crossing the legs, sleeping or sitting in a position that causes compression or stretching of nerves, and the use of constricting clothing or vasospastic drugs like tobacco should be avoided by patients with ischemia of limbs. Tingling, numbness and similar mild complaints may indicate early stages of ischemic neuropathy and may therefore be signs of serious import. Benefit may follow vasodilation and correction of causal factors.

Vascular Fragility Tests in Hypertension.—Schweppe and his associates attempted to evaluate the three capillary fragility tests, the Gothlin, the negative pressure and the cuff trauma test. None of the tests adequately fulfils the need for an accurate quantitative test. Abnormal capillary fragility was found in 15.9 per cent of 44 hypertensive patients. Thiocyanates did not increase capillary fragility in this particular series. Rutin, administered in 180 mg. doses daily, reduced the susceptibility to capillary hemorrhage in 3 patients. In 3 the results were questionable. Abnormal capillary fragility was associated with advanced diffuse degenerative arteriosclerosis in most of the cases that were investigated.

Night Cramps in Human Extremities.—Moss and Herrmann present observations on 20 patients with nocturnal muscle cramps. Night cramps seem to result from the action of some end product of metabolism, as in diabetes, or from poor elimination of normal end products of muscle metabolism, as in patients with venous stasis due to varicose veins or pregnancy, or following deep venous occlusion. Increased muscular activity favors the development of night cramps during the rest which follows such activity. No relationship exists between intermittent claudication and muscle cramps at rest. Quinine sulfate has been found to give prompt relief of night cramps in extremities. Evidence indicates that the action of quinine is directly on muscle, rather than on the myoneural junction. Quinine sulfate produces a refractory period in skeletal muscle that is similar to the refractory period in heart muscle.

Endocrine Changes in Cirrhosis of Liver.—Lloyd and Williams studied the endocrine functions in 71 patients with cirrhosis of the liver. Fifty-five of the subjects were men and 16 were women. Decrease in libido and potentia were found in 37 of the 52 men, who could be questioned in this respect. Decrease in the axillary hair growth was present in 46 of 55 male patients. Testicular atrophy was present in 36 of 50 men. Gynecomastia was present in 23 of 55 men. The women with hepatic cirrhosis had alteration in the menstrual pattern, in sexual drive, in body hair, in the uterus and in other target organs of estrogen, including the breast. Reviewing the results of postmortem examinations on 87 patients with Laennec's cirrhosis who were examined at the Mallory Institute of Pathology, the authors say that almost all had a decrease in the liquid content of the adrenals and in 8 of 23 patients there was atrophy of the testes.

Complications of Alkalosis.—Grace and Barr call attention to the fact that the use of gastric suction and sodium lactate solutions may lead to alkalosis which may be accompanied by changes in personality, delirium, stupor or convulsions and by renal insufficiency which tends to persist. The state is often unrecognized and if neglected may lead to serious consequences. The authors present the histories of 9 patients, of whom 6 exhibited both delirium and renal insufficiency, 2 showed delirium only and 1 had renal insufficiency without mental disturbance. Primary conditions included subtotal pancreatectomy, intestinal obstruction, cancer of the colon and peptic ulcer. Three of 4 patients with peptic ulcer were also emphysematous. It seems that emphysematous patients are more than ordinarily susceptible to alkaline therapy. In 2 of the emphysematous patients with peptic ulcer, the administration of Sippy powders or similar alkaline treatment seemed to be the exciting cause. The alkalosis may correct itself if the cause can be removed. In several patients spontaneous remission occurred when the alkaline powders were withdrawn or the gastric suction and parenteral administration of lactate solution were discontinued. In others it appeared necessary to administer autoclaved 2 per cent solution of ammonium chloride in distilled water. The usual procedure was to administer a liter of such a solution (20 Gm. ammonium chloride) over a period of two and one half to three hours. The results were satisfactory and frequently dramatic, with almost immediate improvement in the orientation and cooperation of the patient as well as rapid disappearance of the disturbing symptoms.

Electrolytes in Edema.—Farnsworth collected data on electrolyte partitions in the urine of patients with congestive heart failure, hepatic cirrhosis and nephrosis for the purpose of demonstrating renal function in fluid retention associated with these entities. Clearance evaluation of sodium and chloride in cardiac decompensation and in normal subjects showed a decrease in sodium clearance with respect to chloride in the cardiac group. Comparison of sodium to chloride in milliequivalent ratios showed a constant decrease in sodium excretion and a depression in the sodium-chloride ratio. This depression varied directly with the severity of the disease process and the degree of fluid retention. These results are compatible with the hypothesis that edema is a result of retention of sodium by the renal tubules rather than of increased venous pressure. Patients with hepatic cirrhosis were found to release greatly reduced amounts of sodium; several showed only traces. In this group the sodium-chloride ratio was even more sharply reduced than in the cardiac group. Such evidence of pathologic physiology in the kidney is difficult to reconcile with the widely held theory that fluid retention in cirrhosis is inversely proportional to the plasma albumin concentration. No disturbance in the normal sodium-chloride ratio could be found in 9 patients with nephrosis. It was concluded that fluid retention in cardiac decompensation and in hepatic cirrhosis is not due solely to increased hydrostatic and decreased oncotic pressure, respectively, but to disturbance of electrolyte metabolism intimately associated with the renal tubules. Thus the kidney seems to play an active role in the establishment and maintenance of certain types of fluid retention.

Tumors of Carotid Body.—LeCompte points out that tumors of the carotid body or glomus caroticum have been called by many names, including perithelioma, endothelioma, angioma, chromaffinoma, adenoma, paraganglioma, pheochromocytoma and sympathoblastoma. The variety of names reflects the current confusion regarding the development, structure and function of the carotid body. The carotid body is a chemoreceptor, not a gland of internal secretion, and is not part of the "chromaffin system." In a series of 17 tumors of the carotid body no true chromaffin reaction was demonstrated, and no evidence for the secretion of epinephrine was obtained in assay of the fresh tissue in 2 instances. Tumors of the carotid body exhibit a basic pattern of nests of principal cells surrounded by a more or less vascular stroma. Depending on the relative amounts of principal cells and stroma, they may be described as usual, adenoma-like or angioma-like. Use of the noncommittal term carotid body tumor is preferred to other names generally used. The great majority of these tumors are both histologically and clinically benign. In view of the high operative mortality it is doubtful whether they should be removed in those cases in which ligation of the carotid arteries is necessary.

Clinical Examination in Recognition of Heart Disease. B. Manchester. -p. 429.

Ulcers of Leg in Mediterranean Disease.—Estes and his co-workers of the Mayo Clinic report observations on 3 sisters of Italian descent, aged 30, 23, and 19, respectively. All 3 at one time or another had had ulcerations of the skin of the legs. Local treatment for the ulcers and the administration of iron, liver extract and whole blood had not brought about any improvement in the ulcers or the general health of the 3 patients. In smears of specimens of blood from all 3 patients similar changes characteristic of Mediterranean disease, better known as Cooley's anemia, (familial erythroblastic anemia) were seen. These changes consisted of a great variation in the size and shape of erythrocytes, with many microcytes but no spherocytes. Hypochromasia and polychromatophilia were well defined, and normoblasts were present. Target cells were seen in all smears, but they were not conspicuous. The diagnosis of Mediterranean disease was made on the basis of familial anemia, increased resistance of the erythrocytes to hemolysis in hypotonic solution of sodium chloride, exceedingly active normoblastic erythropoiesis, and the failure of the anemia to respond to therapy. No other cause for the anemia could be found. Sickle cell anemia was eliminated by the absence of sickling, and congenital hemolytic icterus, had it been present, should have produced sperocytosis and increased fragility of the erythrocytes. Cutaneous ulceration of the legs of patients with Cooley's or Mediterranean anemia has not been described before. The observed cases prove the existence of this symptom. Such ulceration cannot be distinguished grossly from that occurring in sickle cell anemia and congenital hemolytic icterus. The outstanding histologic feature noted at biopsy of one of these ulcers is the prominent deposition of iron in the cutis. The authors conclude that the chronic ulcer on the leg of an anemic patient is not pathognomonic of a specific type of anemia. The exact character of the anemia must be determined by appropriate clinical and hematologic study.

Major Trigeminal Neuralgia.—Davis and Naffziger say that major trigeminal neuralgia has been recognized as a clinical entity since Fothergill's classic description in 1776. They review 245 cases that have been observed at their hospital. The highest incidence was observed in patients aged between 50 and 60 years. The average duration of symptoms was around seven years. There was a sudden onset of jabbing, cutting, burning, lightning-like or electric-shocklike pain which radiated over one or more divisions of the trigeminal nerve. The radiation was to the peripheral distribution. The pain stopped as suddenly as it began. There were several patients who noted a peculiar prickling, burning, throbbing sensation for days or weeks prior to the first sharp pain. Treatment was primarily surgical. Alcohol was injected in 175 cases. Many patients had multiple injections. The longest period of relief following an injection of alcohol was seven years. The average duration of relief was from six to fourteen months. Neurectomies were performed in 50 patients. These were mainly supraorbital, infraorbital and inferior alveolar neurectomies. The period of relief averaged the same as with alcohol injection. Sensory root sections were done in 179 patients. In most of these either alcohol injection or neurectomy had been performed previously. If the pain is completely relieved by alcohol injection, the diagnosis is established and sensory root section can be carried out with confidence that the pain will be permanently relieved. The anesthesia produced by the injection also serves to accustom the patient to the permanent anesthesia produced by root section. Some patients who were poor operative risks have been kept in comfort by repeated alcohol injections over a period of years. It is believed that the procedure of choice is a differential section of the sensory root with sparing of the motor root.

Treatment of Epilepsy.—Aird reports observations on 75 patients in whom methylphenylethyl hydantoin ("mesantoin") was used. The sodium salt of diphenylhydantoin had proved ineffective or toxic. Other anticonvulsive agents used with "mesantoin" were given in the same optimal doses and combinations that had been worked out prior to the addition of the new agent. Toxic symptoms appeared in 7 patients and the hydantoin derivative produced no appreciable benefit in an additional 8 patients. Eighty per cent of grand mal seizures were improved, 78 per cent of jacksonian seizures were helped and 79 per cent of psychomotor seizures were benefited. Sixteen patients with petit mal appeared to derive some benefit, but the improvement was great in only 7 of these. The limited results on petit mal forbid any final evaluation of the hydantoin derivative against this type of seizure. These results are comparable with those obtained in other studies on this new anticonvulsive agent. The great value of the drug in convulsive states other than petit mal and its relatively low toxicity suggest that it will prove a valuable substitute for "dilantin." Although of low toxicity if used cautiously, "mesantoin" may be associated with alarming toxic symptoms. One fatal case of aplastic anemia occurred in this group.

Thrombosis-Embolism Problem in Hip Fractures.—Bishop presents the case of a woman, aged 76, who died during manipulation of a hip that had been fractured for eighteen days. Thrombosis had not been suspected. Since this is a common type of fracture in the aged, and since many such patients are not manipulated or operated on for several days or weeks following time of injury, it was thought that perhaps other similar types of death might be explained on the basis of thrombosis and embolism. A search for similar cases has been maintained by careful scrutiny of the literature and close questioning of orthopedic, geriatric and anesthetist physicians. A total of 17 cases has been collected in which death occurred from pulmonary embolism during or shortly following operative procedures on fractured femurs. Necropsies substantiated this diagnosis in 14 cases of this series. The embolus was fat in 3 instances. Death was sudden and occurred during operation (without forewarning) in 11 of the 17. The ages of the patients in this series ranged from 35 to 86 years. The author points out that a relation exists between the elderly patient confined to bed with a hip fracture and thromboembolic disease and that the longer operative treatment is delayed following injury, the greater will be the possibility for thrombosis to develop in the fractured extremity. If the fracture is old, preventive measures should be instituted prior to surgical procedures. These might include the use of anticoagulants, venous ligation or mobilization of the patient. A plea is made for early ambulation in all elderly patients suffering from fracture of the hip. Rest in bed should be considered unphysiologic in the management of hip fractures in the aged.

Psychologic Factors in Motion Sickness.—Wendt states that the character of the motion, the posture of the head and the physiologic state are major determiners of motion sickness rates. The Army and Navy personnel who were the subjects of these experiments did not get sick, even though psychologic factors were present, unless the combination of physical and physiologic factors was appropriate. Although psychologic factors are operative, physical and physiologic factors outweigh them in practical importance. The view that airsickness is " all psychologic " is a defeatist position. In practice, psychologic preventive measures are sometimes a failure. Such procedures should be used, but fewer miracles are to be expected of them than from manipulation of the physics and physiology of the situation. After citing several psychologic factors that would help in overcoming motion sickness, the author stresses the importance of a better understanding of the kinds of motion that produce sickness, followed by changes in design and operating procedures, a better understanding of the role of posture, followed by routine adoption of favorable postures when the motion becomes unfavorable, and better understanding of the physiology of motion sickness so that prophylactic drugs may be studied.

Antisyphilitic Activity of Penicillins F, G, K and X and of Bacitracin.—Eagle and Fleischman inoculated rabbits intradermally with Treponema pallidum, and treated them four days later with intramuscular injections of the various penicillins or bacitracin, repeated once daily for four days. The doses of penicillins F, G, K and X and of bacitracin that aborted infection in half the animals were, respectively, 3.5, 0.3, 2.6 and 2.2 mg. per kilogram of body weight and 90 units per kilogram. The absolute and relative activities of the various penicillins and bacitracin varied widely according to the method of assay. Penicillin G was by far the most effectively antisyphilitic of the compounds tested.

Mold Arthroplasty of Hip Joint.—Smith-Petersen says that a benign reaction to an inert foreign body (glass) gave rise to the thought that here was a process of repair which might be applied to arthroplasty. A mold of some inert material, interposed between the newly shaped surfaces of the head of the femur and the acetabulum, would guide nature's repair so that defects would be eliminated. The original glass molds were abandoned because of easy breakage, and the use of other materials was discontinued because of foreign body reaction. In 1938 the first "vitallium" mold arthroplasty was performed, and since then over 500 hips have been operated on by this method at the Massachusetts General Hospital. The fact that this operation has been performed on such an extensive scale is evidence that the results have been satisfactory. Malum coxae senilis, rheumatoid arthritis, complications of fractured hips, old septic hips, congenital dislocations and practically all conditions to which the hip joint is subject were treated by this operative procedure. Fifty-three patients have been subjected to revisions of the first arthroplasty. Calcification of the rectus tendon made some of the revisions necessary. Furthermore, the need for a relatively large acetabulum was not fully appreciated at first. Many patients with rheumatoid arthritis have undergone operation a second time because of a decreasing range of movement. Sepsis has been responsible for a small number of revisions. There has been no operative mortality in these 500 arthroplasties.

Postoperative Study of Mold Arthroplasty.—Law carried out a detailed study of "vitallium" mold arthroplasty of the hip joint. In this series of 150 cases of arthritis of the hip joint treated by "vitallium" mold arthroplasty (182 arthroplasties), 80 per cent of late results are satisfactory. Striking features are the relative painlessness, smooth movement of the hip joint, formation of the joint lines as seen radiographically in the postoperative period. Function of the hip joint after arthroplasty for traumatic and degenerative arthritis approaches the normal much more closely than in cases of infective and rheumatoid arthritis. There is a complete absence of low back symptoms or postural difficulties, and there is no difficulty in preventing stiffness of the knee joint. Different technical procedures are indicated according to the degree of absorption of the femoral head or neck, and the stability of the mold in the acetabulum. The operative mortality rate in this series was nil, and during the six year follow-up period only 1 patient died as the result of a complication of the arthroplasty. Secondary operative revisions are often necessary, particularly in cases of infective and rheumatoid arthritis.

Penicillin in Hematogenous Osteitis in Children.—Dennison says that during the first eighteen months in which penicillin was available in the Glasgow Royal Hospital for Sick Children, 56 patients with osteitis were treated in one surgical unit. Of these, 30 patients had severe toxemia; in 9 the bone lesion was the outstanding feature and toxemia was slight; the remaining 17 were admitted for the treatment of chronic pyogenic bone infection. The term osteitis is used as meaning acute or chronic infection of bone tissue; it includes the conditions known as osteomyelitis and periostitis. The affected part was immobilized until radiographic examination showed sound consolidation, that is, for periods of from two to eight months. During the first twelve months, penicillin was given by continuous intramuscular drip for ten to fourteen days. Subsequently, owing to difficulties with drip infusions, the author reverted to intermittent intramuscular injection. Administration of penicillin was continued for twenty-one days, or until the marrow culture was reported sterile, and the total dose varied from 1.1 to 8.4 mega (million) units according to age. If pus was present in soft tissues when the patient was admitted, general penicillin administration was started and the limb was immobilized. Pus was evacuated within twelve hours by aspiration or incision. Each morning aspiration through the indwelling tube was attempted and the fluid was sent for culture and penicillin assay; 100,000 units were again instilled. If there was no evidence of pus formation in the soft tissues the limb was immobilized and general penicillin therapy was instituted. If, pain, tenderness and signs of toxemia were not relieved within forty-eight hours, operative treatment was undertaken in order to reduce the tension of pus under the periosteum. Increasing swelling, tenderness or erythema was obvious indication for surgical intervention. Bone drilling was performed in 6 instances--always with dramatic relief from pain. Sequestrum formation requiring surgical intervention occurred in 6 cases. All wounds remained healed after primary suture. There were no deaths, pathologic fractures or ankylosed joints in the patients with acute osteitis. The average hospital stay was thirty-two days.

Local Use of Bacitracin.—Miller and his coworkers report the clinical results and the bacteriologic data in a study of 165 patients treated with bacitracin in an ointment base They found that bacitracin ointment, 480 units per gram, is an effective agent against superficial pyogenic infections. In impetigo the median time of cure with bacitracin ointment of eight days compares favorably with six days when penicillin or sulfonamide ointments were used. The bacitracin ointment caused a contact type of dermatitis in less than 1 per cent of cases. Patch tests after treatment, even at sites of former dermatitis, were all negative. The effectiveness and low sensitizing potential of bacitracin suggest its trial against infectious eczematoid dermatitis, folliculitis, vesiculopustular eruptions of the hands, and in the secondary infections accompanying many dermatoses. In general, organisms known to be sensitive to penicillin were found to be sensitive to bacitracin.

Allergic Carditis, Pericarditis and Pleurisy: Report of Case of Serum Sickness with Predominant Cardiac Manifestations and Symptomatic Recovery. Preliminary Report. C. A. McKinlay. -p. 61.

Histamine Antagonists in Allergy.—Based on the concept that allergic symptoms are due to histamine action, attempts have been made to treat the allergic patient with various histamine antagonists. Criep says that "hapamine," histaminase, "anthallan" (a benzofuran derivative) and histamine itself are of little value. "Benadryl," "pyribenzamine," Nu 1504 ("thephorin") and "thenylene" have proved useful only in the symptomatic treatment of certain allergic disorders. These are acute and chronic urticaria, the urticarial lesions of serum sickness, insulin and drug allergy, the pruritus of atopic dermatitis, seasonal hay fever and allergic rhinitis. The side actions evoked by these drugs limit their scope of usefulness. Some of their effect may be due to their sedative action. They do not prevent or alleviate the development of asthma in pollen-sensitive patients.

'Metrazol" for Barbiturate Poisoning.—Engstrand and Hruza report the case of a woman, aged 41, who had taken 30 to 35 tablets of phenobarbital, or about 52 grains (3.36 Gm.), with suicidal intention. She was hospitalized in deep coma about forty-five minutes after she had taken the tablets. The stomach was immediately lavaged with 2 quarts (2,000 cc.) of isotonic solution of sodium chloride, and magnesium sulfate was instilled. She was given apomorphine without effect. Picrotoxin was administered at the rate of 1 mg. per minute with a total dose of 45 mg. Improvement in the rate and depth of the respirations and in the color of the patient resulted, but the reflexes remained absent. An ampule of 25 per cent solution of nikethamide was also given without apparent effect. The patient remained comatose. Evidence of pulmonary edema with frothing at the mouth was noted. Oxygen by nasal catheter and various supportive measures were continued for many hours, but she remained comatose and cyanotic. "Metrazol" (pentamethylenetetrazol) 5 cc. was injected intravenously and repeated fifteen minutes later. This resulted in some improvement in respiration. Subsequently more of the drug was given, a total of 80 cc. in divided doses being administered over a period of eighteen hours. The patient recovered and six months later was gainfully employed.

Growth of Children with Diabetes Mellitus.—Beal analyzed the growth records of 200 children under treatment for diabetes mellitus and compared them with the body size and growth rates of normal children. The data for both groups were collected in Iowa between 1928 and 1945. Children who acquire diabetes mellitus are of normal height for age at the time of onset of the disease. The heights of children who were *first examined between six months* and three years after the onset of diabetes mellitus differed from normal height for age by an average of minus 1.1 inches (2.8 cm.); of children first examined more than three years after onset, by an average of minus 3.9 inches (9.9 cm.). These observations demonstrate a relationship between height and the duration of untreated or inadequately treated diabetes. The mean annual gain in weight for diabetic children between the ages of 5 and 7 years was slightly less than the gain for normal children. The mean annual gain for the diabetic children between 7 and 9 years of age was substantially less than for normal children. The diabetic boys were, on the average, 1.9 inches (4.8 cm.) shorter than normal boys at 17 years of age. However, later than normal growth in height enabled them to achieve an average gain of 1.7 inches (4.3 cm.) after 17 years of age. As a result of this gain, their mean adult height was essentially the same as normal adult height. The diabetic girls deviated from normal by an average of ½ inch (1.27 cm.) at 16 years of age and gained an average of 0.6 inch (1.5 cm.) after age 16. Thus, although both sexes were, on the average, shorter than the normal height at the time that growth is usually terminated for the normal child, additional gains led to the attainment of normal adult stature.

Megaloblastic Anemia in Infancy.—According to Siebenthal true pernicious anemia is seldom observed in infants. It differs from other macrocytic anemias, including megaloblastic anemia. This megaloblastic anemia is a temporary deficiency of the antianemic principle. The condition is seen most often in infants between 2 and 16 months of age. The child with megaloblastic anemia exhibits pallor, weakness, irritability, persistent upper respiratory infection and extreme loss of appetite. These infants have a severe normochromic anemia with many macrocytes. The bone marrow shows erythropoiesis to be megaloblastic. The author reports 2 infants with megaloblastic anemia. Both responded favorably to treatment with folic acid. The infant 6 months of age was given 5 mg. of the drug and the infant aged 16 months, 10 mg. orally twice a day. A prompt reticulocyte response was demonstrated, followed by a gradual rise in hemoglobin and red blood cell level. The folic acid therapy was continued for four months in the first infant and only during the thirty days of hospitalization in the second. The further development was satisfactory in both cases. Megaloblastic anemia is a relatively common disease of white infants. A complete and permanent recovery can be effected by folic acid therapy.

Glass Button Operation in Ascites.—Lane believes that many patients with ascites are in no condition to undergo major surgical procedures. For this reason, the glass button operation has been tried with a certain amount of success. It consists of implanting one or more buttons or spools made of glass in the abdominal wall, so that the ascitic fluid may drain directly into the subcutaneous tissues. The author has used this procedure in 7 cases. Two of these were failures. Three have had fair to moderate results. Three have had excellent results with complete disappearance of edema and ascites; these latter 3 went into positive nitrogen balance as they gained weight without accumulations of fluid. The author admits that the procedure has its faults and does not always work, but it is a minor procedure that can be carried out in patients who are poor surgical risks. It does relieve increased intra-abdominal and intrathoracic pressure. It does allow partial restoration of protein balance.

Otic Complications of Streptomycin Therapy.—According to Snell, complications of streptomycin therapy include vertigo, tinnitus, impaired hearing, blurring of vision, eosinophilia, circumoral pruritus, dermatitis, angioneurotic edema, albuminuria and granular casts in the urine. Vertigo seems to be the most lasting of these complications. Closely associated with this vertigo or dizziness is blurring of vision. The St. Louis Streptomycin Conference held in May 1947, and sponsored by the National Research Council, presented 809 cases which had been treated according to the old regimen, which consists of dosage scale of 2 Gm. of the agent daily for one hundred and twenty days. Of these, 96 per cent showed subjective and objective symptoms of vestibular damage. The damage ranged all the way from those patients who showed only objective symptoms (caloric test) to those who were so affected that the drug was discontinued. As yet no data are available as to the permanence of this damage, but fortunately, the patient seems to recover from deafness in the majority of cases.

Osteoid Osteoma.—Goldenberg says that in the twelve years which have elapsed since Jaffe first described the clinical and pathologic characteristics of a benign tumor which he designated as osteoid-osteoma, 141 cases have been reported. An osteoid-osteoma is usually about a centimeter in diameter. The tumor has been found in almost all bones but is more commonly observed in the lower extremities. The pain, usually mild and intermittent at the time of the onset, may be aggravated by activity. Later the pain becomes constant and increases in intensity. In early cases the roentgen examination discloses a small oval area of rarefaction surrounded by a zone of sclerosis. In 3 of Goldenberg's 4 cases a history of trauma was elicited. Three of the 4 patients were treated surgically, and the symptoms subsided in each of these. The fourth case is incomplete, in that operation was postponed on account of pregnancy. The symptoms in this case had persisted for ten years. Because of the small size of the lesion it is imperative that roentgenograms be available in the operating room for accurate localization and for postoperative assurance that the tumor has been completely excised. The removal of the sclerosed bone does not appear to be necessary as long as the nidus has been removed.

Thrombophlebitis Migrans in Carcinoma of Stomach.—The Baums and Hermann discuss the syndrome of migrating thrombophlebitis in association with carcinoma. Carcinoma of the body or tail of the pancreas is most frequently implicated in this syndrome, but carcinoma of the stomach is sometimes the etiologic factor. A case of carcinoma of the stomach with symptoms of migrating thrombophlebitis and few gastrointestinal complaints is reported. Because of anemia and migrating thrombophlebitis, a presumptive diagnosis of carcinoma of the body or tail of the pancreas was made, and an exploratory laparotomy was performed. A carcinoma of the stomach was found on the lesser curvature near the cardia with metastases to the regional lymph nodes and the left lobe of the liver. The patient had an uneventful postoperative course. At home his course was slowly downhill with gradual emaciation and episodes of thrombophlebitis involving the left femoral and left subclavian veins. Terminally a cord bladder was noted, due either to metastatic involvement or possibly to thrombosis of spinal cord veins.

Protein Nutrition and Conservation.—Kinsman points out that proteins are unique among the three classes of food substances (carbohydrates, fats and proteins) because they alone contain the most important raw materials, the amino acids out of which the complex tissues of the body are constructed. Since only protein can furnish amino acids for the building of body tissues, it is obvious that the protein requirement is greatest when new tissues or secretions are being formed, i.e., during the growth period and during pregnancy and lactation. The normal adult, man or woman, requires for optimal health only slightly more protein than is sufficient to replace the body and plasma proteins that are being broken down in tissue metabolism. In infancy and childhood protein requirements are much higher in relation to body weight. When protein is used for energy it yields approximately the same number of calories per unit of weight as does carbohydrate. When protein-containing foods are scarce, it is obviously unsound practice to use protein for energy. It might be more economical to obtain sufficient calories from carbohydrates and fats to meet the energy requirements of the body. The protein, supplied in an amount sufficient to meet the specific protein requirement, is then available for the repair and building of body tissues. If enough calories from carbohydrate and fat sources are not provided in the diet, the ingested amino acids will be used for energy.

Sympathectomy in Thromboangiitis Obliterans.—Cooper and Harris performed 186 sympathectomies on 113 men between the ages of 20 and 46 who had thromboangiitis obliterans. The duration of symptoms varied from one month to thirteen years. Both lower extremities were involved in 62 patients, one lower extremity in 45, one lower extremity and one upper extremity in 2, both lower and upper extremities in 4. Spinal anesthesia vasomotor tests to demonstrate the proportion and the pattern of organic and functional spastic elements of the disease in a given patient were performed before surgical intervention. All patients showed a rise in temperature of the feet during the test, the magnitude depending on the degree of vasospasm as well as the extent of development of collateral channels in the extremity. No instances of drop in skin surface temperature were encountered. Sympathectomies were performed on all patients who had ulcerations or gangrene. Bilateral lumbar sympathectomies were performed on all patients showing advanced arterial change in one lower extremity, even though only slight change was present in the opposite extremity. Division of the rami communicantes to the second and third dorsal ganglions and division of the chain below the third ganglion were performed for all operations on the upper extremities. All patients were admonished to abstain completely from the use of tobacco in any form. Additional therapy consisted of whiskey in small amounts four times daily and local care of the ulcers or gangrenous areas. After sympathectomy there was immediate relief of the unbearable aching and burning. The pain which persisted was described as a slight burning sensation which did not interfere with sleep and which was easily controlled by mild sedatives. Edema of the foot rapidly subsided. Healing of the wounds was rapid. In no instance was there a progression of gangrene following operation if the patient had stopped smoking. All patients appreciated the warmth of the extremities and the increased tolerance for cold. Major amputations were obviated in all patients except 3 in whom gangrene of a large portion of the foot had developed prior to sympathectomy. Sympathectomy is the treatment of choice in thromboangiitis obliterans.

Solitary Nodule in Thyroid.—According to Soley, Lindsay and Dailey, the single nodule in the thyroid is regarded by some as of the same significance as a nodule in the breast. It arouses suspicion because of the possibility of cancer. At the thyroid clinic of the University of California Hospital 96 patients with solitary thyroid nodules were seen between 1935 and 1944. Pathologic studies of the nodules showed 38 to be involutionary, 21 to be adenomas and 15 to be malignant neoplasms. In addition, 18 could not be classified as either involutional or neoplastic in origin. Rapidity of growth, coincidental appearance of goiter and symptoms, residence in an endemic goiter region, a family history of goiter, age, clinical history suggesting hemorrhage into a nodule, pressure symptoms and texture of the nodule were not as helpful as might be expected in the clinical differentiation of involutionary from neoplastic nodules. The singleness of the nodule is the most important factor. A solitary nodule in the thyroid should be radically resected.

Obtaining Bone Marrow from Vertebral Spinous Process.—Huss and his co-workers found that a method for obtaining marrow from the vertebral spinous process was in use in Japan. This technic had been extensively employed by the hematologist Nakao and his associates of Tokyo Imperial University. Its origin is apparently Japanese. The utility and simplicity of the method are impressive: (1) the patient faces away from the operator and is not disturbed by the sight of the needle; (2) the momentary pain when suction is exerted is less in the spinous process than in the sternum, (3) draping of the field is not necessary; the patient cannot breathe on the operative site, (4) the spinal column offers much more rigid support than does the sternum, (5) the cortical lamina of the spinous process is thinner and easier to penetrate than is the sternum; and (6) vital structures are removed by many centimeters from the point of entrance into the bone. With the sternal method penetration of the sternum has occasionally occurred with mediastinal hemorrhage, and there have been accidents from injury of the internal mammary artery. The authors made a statistical comparison of the differential counts of the sternal and of the vertebral bone marrows on 25 persons, 15 of whom were healthy and 10 were patients. They conclude that marrow comparable to that from the sternum may be obtained, although there is considerable variation in the differential counts, as there is in successive sternal punctures from the same patient. Vertebral puncture has additional value for the detection of tumor cells metastatic from the prostate or other organs.

Reconstruction of Mutilated Hands.—Rank and Wakefield show that in the management of destructive hand injuries, consideration must be given to the possibilities of reconstruction or substitution for parts that are lost. Many of the ingenious and tedious operations that have been carried out on mutilated hands have a rare application; but some have become procedures, to be known and considered by all concerned with hand injury and repair. One such procedure concerns restoration of the "pinch" function to a mutilated hand by plastic reconstruction of an opposition digit or digits. The "pinch", or opposition, function in a normal hand involves essentially the function of a normal thumb. For this three considerations must be satisfied: (1) the thenar muscles must be present and in a functioning state; (2) there must be an adequate length of thumb; (3) there must be present an adequate length of finger or fingers to which the remaining length of thumb can become apposed. Many wounded hands are left without "pinch" function by reason of defects in one or more of these three factors; but provided the first factor is satisfied their "pinch" function can still be restored. A free thumb can be remade or adequately lengthened, or a rigid digit can be made to which the thumb element may be apposed. Discussing the reconstruction of an opposition digit, the author describes: the raising of a tube pedicle; the attachment of the pedicle to the hand; the detachment of the pedicle from the abdomen; the bone graft, and the aftercare.

*Cardiac Catheterization in Cases of Patent Interauricular Septum, Primary Pulmonary Hypertension, Fallot's Tetralogy and Pulmonary Stenosis. Sheila Howarth, J. McMichael and E. P. Sharpey-Schafer. -p. 292.

Prognosis of Patent Ductus Arteriosus.—Benn reviews observations on 46 cases of patent ductus arteriosus, which he divides into two groups. Group A includes 30, all except 1 of which had been collected from a school cardiac clinic. This probably includes every case of patent ductus arteriosus among the younger people of Bristol, whether they had symptoms or not. Group B consists of 16 cases from areas outside Bristol referred in a few cases from school clinics but often because of symptoms. Thus group A forms a representative sample of the condition while group B approximates more nearly the type of case generally reported. The author gives particular attention to the 30 patients of group A. Here females predominate over males by more than two to one. The absence of bacterial endocarditis in group A suggests very strongly that it is much less common than has been described. Most patients lead a normal life, but many are below average weight. Bacterial endocarditis has become much less dangerous since the discovery of penicillin. Operation with its grave risks hardly seems justified merely for the prevention of the possibility of infection. However, patients cured of bacterial endocarditis appear to be proper subjects for operation as they are probably more liable to, or more exposed to, infection. In 2 cases the classic murmur disappeared without other evidence that the ductus arteriosus had closed. Precordial thrills sometimes vanish with increasing age. The diastolic blood pressure is usually normal. Pulmonary congestion is not so common as has been reported. The average body weight is significantly below normal. Operation is required in only a limited number of cases of patent ductus arteriosus. The following are indications for surgery: bacterial endocarditis, recovered bacterial endocarditis, cardiac embarrassment or poor physique.

Cardiac Catheterization in Patients with Intracardiac Shunts.—Howarth and her associates point out that the development of the technic of cardiac catheterization indicated a method for the detection of intracardiac shunts. They report data on patients that were suspected on clinical grounds of having intracardiac shunts. Samples of blood from the right auricle and right ventricle may be obtained by cardiac catheterization in cases of suspected cardiac shunts. Blood so obtained contains more oxygen than vena cava blood if the shunts is from left to right. Right to left shunts may be detected by a reduced arterial oxygen saturation in the presence of normally functioning lungs. Two of the 5 cases with patent interauricular septum showed a conspicuous increase in right auricular pressure with the shunt still left to right. A case with enlarged pulmonary arteries and a normal arterial oxygen saturation showed no evidence of a shunt and a greatly increased mean right ventricular pressure. A diagnosis of pulmonary hypertension was confirmed at necropsy. A case of Fallot's tetralogy showed an increased mean right ventricular pressure. The data suggested some left to right mixture of blood, although the main shunt was from right to left. A child with enlarged pulmonary arteries showed no evidence of a shunt. Mean right ventricular pressure was greatly increased and a diagnosis of pulmonary stenosis was made. A case of patent ductus arteriosus showed a greatly raised mean pulmonary arterial pressure, a considerably raised right ventricular pressure and highly oxygenated pulmonary arterial blood samples.

Nicotinic Acid in Treatment of Chilblains.--According to Gourlay the usual sites of chilblains are the dorsal aspects of the proximal phalanges of the hand, the plantar aspect of the toes, along the inner border and dorsum of the great toe, and in the region of the heel and achilles tendon. Chilblains may also occur on the ears, but in this site they resemble frostbite rather than a true perniosis. The gross pathology of the chilblain lesion is a vasoconstriction of the subcutaneous arteries and larger arterioles associated with a vasodilation of the superficial minute vessels. Having observed the vasodilator action of nicotinic acid, the author decided to use it in the treatment of the cold congested hands and noses from which so many young children suffer in the winter; the results were dramatic. The basic dose of nicotinic acid administered was for an adult 50 mg. and for a child 25 mg. thrice daily immediately after meals; this tended to reduce the incidence of flushing and caused a prolongation of the vasodilator action of the nicotinic acid. In severe cases the dose was increased, but in no case was it found necessary to give more than 300 mg. a day. Relapse was common when the nicotinic acid was withdrawn. Twenty-seven cases are reviewed. It is suggested that nicotinic acid is the method of choice in general practice owing to its ease of administration and its freedom from serious untoward effects.

Psychologic Aspects of Sydenham's Chorea.—Walker believes that the hardening of opinion in favor of a toxic infective theory of Sydenham's chorea which followed on the development of bacteriology, is unjustified. Certain sociologic factors in relation to 131 children treated for chorea in the Royal Aberdeen Hospital for Sick Children between 1930 and 1942 have been considered, and the influence of war conditions on the incidence of the disease in the northeastern part of Scotland. A more thorough and detailed investigation into the life circumstances of 42 of these children revealed that in every instance the child was subjected over a considerable period of time to conditions calculated to induce functional nervous disturbance. These results are shown to be similar to those of recent investigations of the same kind by pediatricians and to support the conclusion reached by many of these investigators that chorea is probably a psychologically determined disease.

•Occurrence of Foot and Mouth Disease in Hedgehog Under Natural Conditions. J. D. McLauchlan and W. M. Henderson. -p. 474.

Absenteeism in Women Workers.--Wilson studied factors leading to loss of working time in a group of 144 women factory workers. The majority were single women whose interests centered in their families. One third of these 144 women, owing to disability of some near relative, had home duties which were sufficiently heavy to interfere at times with their factory work; a contributory cause of absenteeism was ill health, ascribed by many workers to cold and draughty working environment. Examination of the factory records showed more than twice the rate of absenteeism due to certified sickness among women with home ties and responsibilities.

Foot and Mouth Disease in Hedgehogs.--McLauchlan and Henderson say that foot and mouth disease was observed in hedgehogs (Erinaceus europaeus) in connection with outbreaks of the disease among farm stock in Norfolk during the summer of 1946. It seemed probable that affected hedgehogs were responsible in some instances for spreading the disease to cattle.

Antibiotic Bacterial Strains from Human Sources.-Reiter and Boxer have isolated three bacterial strains from human sources, which exhibited considerable antibiotic activity. One belongs to the Bacillus brevis group and proved antagonistic mainly to gram-positive organisms. It has been isolated from mesenteric lymph nodes with reticuloendothelial hyperplasia. An extract prepared from the culture was not only antibiotically active but stimulated also the reticuloendothelium in rabbits. Two strains of Pseudomonas fluorescens, predominantly antagonistic against gram-negative organisms were isolated from stools. The administration of living cultures to patients with enteric infections appeared to shorten the disease if the cultures were given after the bacteremic stage had passed but was without effect during this period of the disease

Eosinophils in Detection of Intolerance for Arsphenamine.—In investigating the problem whether the eosinophils in the blood are of value in the recognition of an intolerance for arsphenamine, Kleifeld directs attention to considerable margins of error with various methods of counting eosinophils. Clinical observations have revealed that neither immediately after nor during an injection of arsphenamine, alone or combined with bismuth, is there any causal relation to the behavior of the eosinophils. Increases, reductions or stationary eosinophil counts were found to be accidental. Consequently, control of the eosinophilic blood picture is of no value for the early recognition of intolerance for arsphenamine treatment and earlier reports to this effect are erroneous.

Tuberculosis and Syphilis.—Sczuka is concerned with the problem whether in case of concurrence of tuberculosis and syphilis the two processes exert influence one on the other. This problem is of vital importance at present, when, as a result of the war, both diseases are increasing. The author discusses similarities and differences between the two diseases with regard to the morphology, biology and dissemination of their causal organisms. She observed that the new, florid, open and exudative forms of tuberculosis promote the dissemination of the syphilitic organism in the body. Tuberculous processes of the skin and the mucous membranes become superinfected with syphilis. Conversely, secondary syphilis, inadequately treated syphilis and old syphilis with organic and visceral symptoms, such as tabes or paralysis, predispose a patient to the acquisition and dissemination of tuberculosis. The author proves this on the basis of literature reports and of 4 cases observed at a hospital in Hannover and presented in this report.

*Epidemic of Meningomyeloencephalitis After Vaccination Against Smallpox. J.L. Keyzer and P.P.M. Nieuwenhuis. -p. 403.
Congenital Atresia of Esophagus. J. Ten Kate. -p. 417

Epidemic of Postvaccinal Meningomyeloencephalitis.—According to Keyzer and Nieuwenhuis 27 cases of smallpox occurred in Belgium in the spring of 1947. Because of this outbreak a large part of the population of the adjoining provinces of Holland (Limburg and N. Brabant) were vaccinated. In the course of these vaccinations 27 patients with postvaccinal encephalitis were admitted to the author's hospital. One patient presented the symptoms of a transverse myelitis. All patients had been vaccinated for the first time. The age varied between 7 and 16 years. The incubation period lasted 11.8 days on an average. Four severe cases are described. The clinical pecularities of all the 27 cases are tabulated. Two patients died. In the others no mental or physical defect remained. The morbidity was very high: one case of encephalitis occurred among 700 vaccinations. The authors recommend compulsory vaccination for children under eighteen months.

*Virginal and Gravidic Hypertrophy of Mamma. A. Diez de Urdanivia M. and D. Gutierrez Garcia. -p. 78.

Virginal Hypertrophy of Breasts.—The condition is rare. It occurs in adolescent girls and in young pregnant women. It is due to special reactivity of the breast to hormonal stimulation. Hypertrophy can be limited to one or several lobes of the breast or be diffuse. In either type the breast grows rapidly. It is painless and soft on palpation. The treatment consists of simple mastectomy followed by plastic surgery. In the limited type of the disease, partial mammectomy followed by plastic surgery is indicated. The histopathologic picture is similar to that of diffuse fibroadenoma. A case in a Negro girl of 13 years of age is reported. Hypertrophy began with appearance of menstruation at the age of 12 years. "Perandren" failed. Within one year the breast was larger than the head of the patient. The histopathologic study of the removed breast confirmed the clinical diagnosis of hypertrophy in adolescent girls.

*Experiences with Retropubic Prostatectomy According to Terrence Millin. F. H. Van Gulik. -p. 9.
Treatment of Diphtheria Bacilli Carriers with Local Application of Penicillin. W. H. Borst. p. 12.

Retropubic Prostatectomy According to Terrence Millin.—Van Gulik reviews the literature on retropubic prostatectomy according to Terrence Millin and says that he himself has performed this operation on 50 patients, of whom 33 could be reexamined. On the basis of his results he concludes that this method should not be compared with the transvesical method of Freyer. He thinks that Millin's retropubic prostatectomy should be used for enlarged prostates and that transurethral resection should be reserved for small prostates. He reemphasizes that Millin's method should be executed only by surgeons well schooled in urologic surgery, not by general surgeons who only now and then operate on the prostate.

Postencephalitic Disturbances in Blood Pressure, Respiration and Metabolism.—Frowein and Harber present the history of a man, aged 30, who during his army service on the Russian front had contracted typhus, which became complicated by encephalitis. Subsequently he had frequent attacks of cerebral convulsions, which became more frequent in spite of antiepileptic treatment. He also had disturbances in blood pressure, pulse rate, respiratory rate, heat regulation, sweat secretion and basal metabolic rate. Investigation of these disturbances made it evident that the considerable increase in the basal metabolic rate was not caused by hyperfunction of the thyroid but was of central origin. The authors cite observations of W. R. Hess, who in studies on the hypothalamus found that the sphere which regulates the circulation coincides largely with that regulating the respiration. Both form a systemic aggregate, and there are connections with the centers of the other sympathetic functions. This indicates that the diencephalon is organized not so much according to organs but according to functional aims. Many functional aims are accomplished by the simultaneous activity of several sympathetic organ systems. This may explain the close connection between the various functional disturbances observed in the present case.

Roentgen Treatment of Peritendinitis Calcarea of Shoulder.—Madsen found this disorder in 81 of 701 patients with painful shoulder examined. There were perhaps more cases, as the importance of roentgen examination with the arm in internal and in external rotation, with comparative pictures of both shoulders, was not recognized at the start. It is an affection of the shoulder with roentgenologically demonstrable calcium deposits in the soft parts. It appears more often on the right side, which testifies somewhat to traumatic etiology, and seems to be mainly a disease of middle and later life, in which occupation plays no part. The clinical symptoms and positive roentgen results establish the diagnosis. In latent cases roentgen examination accidentally reveals a calcification in the soft parts; clinical symptoms often develop later. Peritendinitis calcarea of the shoulder is regarded at least in the acute stage as a clinical entity. Roentgen therapy is an effective and relatively inexpensive method of treatment of a painful and disabling disorder and the results surpass those attained by other methods of treatment.

Dermatology and Syphilis in 1947. F. P. Merklen and P. De Graciansky. -p. 49.
*Falsely Positive Reactions in Syphilis. R. Demanche. -p. 61.
Treatment of Cancer of the Skin. R. Degos. -p. 55

Falsely Positive Reactions in Syphilis.—Demanche agrees with those American authors who do not consider the serologic tests as strictly specific for syphilis, but he stresses the point that falsely positive reactions are exceptional. Falsely positive biologic reactions are nearly always incomplete, dissociated and weakly positive. The Bordet-Wassermann is usually negative; only the Kahn and the Meinicke test may show a partial flocculation. Moreover these false reactions may be temporary and may disappear after weeks or months. Occasionally the false reaction may be permanent and definitely positive; those are the extremely rare cases depending on the serologic constitution of the patient for which Kolmer has coined the term "biologic type." False reactions present a risk which can not be avoided completely, but which can be reduced by serial serum tests which may be repeated weekly or monthly and carried out by two or three laboratories for control purposes; in addition an analysis of the cerebrospinal fluid may be done in certain cases. One should also keep in mind that the serum reaction presents only a symptom and, therefore, it should never be considered as pathognomonic. In cases in which for certain reasons antisyphilitic treatment cannot be postponed, it should be practiced by means of drugs which do not involve any risk, and the patient should be informed that this treatment presents only a test and does not imply a definite diagnosis. In case of premarital examination a person examined may be permitted even to marry provided that his or her nervous system is normal and that the usual precautions are prescribed for the event of pregnancy. The serum reactions although not infallible are of great value and are indispensable. The serologic results should always be considered together with the clinical picture and interpreted in its light.

*Rheumatic Stigma in Endocardium and Myocardium of Apparently Non-Rheumatic Hearts. R. Barahona and M. Gorena N. -p. 2407.

Rheumatic Lesions in Endocardium and Myocardium of Apparently Non-Rheumatic Hearts.--Barahona and Gorena studied 230 hearts removed postmortem from nonselected adults of both sexes. The majority of the patients died between the ages of 21 and 60 years. The method of study consisted in injecting the heart through the coronaries with a 10 per cent colored gelatin solution. The injections were made in non-autopsied heart at a temperature of 36 C. The valvular endocardium and the myocardium were studied microscopically after injections. Thirty hearts with rheumatic valvular deformities were used as controls. Two hundred hearts were apparently non-rheumatic. Vascularization of the cusps, and inflammation or healed inflammatory lesions of the valvular endocardium were encountered in the thirty rheumatic hearts (100 per cent) and in 43 (21.5 per cent) of the 200 normal hearts. Rheumatic lesions were encountered in the myocardium of the thirty rheumatic hearts (100 per cent) and in 80 of the apparently non-rheumatic hearts (40 per cent). Myocardial rheumatic lesions were present in the 43 apparently non-rheumatic hearts whose valvular cusps presented vascularization (100 per cent), and in 37 of the apparently non-rheumatic hearts whose valves presented no vascularization (24 per cent). The authors conclude that the presence of vessels in apparently normal cardiac valves is of pathologic significance and is of rheumatic etiology. Rheumatic disease frequently appears in a given community and produces slight changes in both the endocardium and in the myocardium.

Systolic Murmur Due to Obstruction of the Aortic Orifice. C. Lian. -p. 49.
*Xerophthalmia in Suckling Infants and Hepatic Insufficiency. R. Weekers and R. Houet. -p. 57.

Xerophthalmia in Infants.—Weekers and Houet report 2 cases of xerosis and keratomalacia in male infants aged 3 and 3 and a half months respectively. The first patient was one of twin brothers both of whom received the same food; their intestinal absorption of vitamin A was satisfactory. One of the twins developed a severe icterus; flocculation and serum coagulation tests revealed a severe lesion of the hepatic parenchyma. The xerophthalmia occurred within one month after the icterus. The other twin did not present any liver or eye symptoms. Sixty-thousand units of vitamin A were given daily to the patient; the conjunctival xerosis subsided completely and the keratomalacia improved. The second patient was a premature infant who presented signs of insufficiency of the liver which was enlarged; the urine contained urobilin. The diet of the infant did not seem to be deficient and the intestinal absorption of the liposoluble vitamins was satisfactory. The bilateral keratomalacia was severe, but cicatrization of the corneal lesions resulted from the administration of 60,000 units of vitamin A three times a day. The eye lesions of both patients were not due to an alimentary deficiency or to failure of intestinal absorption of vitamin A. It is suggested that failure of conversion of carotene into vitamin A in the hepatic parenchyma was responsible for the occurrence of the xerophthalmia.

*Correction of Anemia Due to Protein Deficiency, Effect of Casein, Antipernicious Hepatic Factor and Folic Acid Administered at Various Levels. A. Aschkenasy and P. Aschkenasy-Lelu.—p. 514.

Anemia Due to Protein Deficiency.--The Aschkenasys produced in rats a severe hemolytic anemia with considerable erythroblastic reaction in the bone marrow and with terminal normoblastosis of the blood associated with leukopenia and lymphopenia, by placing the animals on a diet completely lacking proteins for fifty to sixty-five days. The rats were then placed on a diet containing casein, antipernicious liver extracts and folic acid. Follow-up of the weight of the animals and blood studies were carried out for thirty to fifty days. Results showed that even far advanced anemia may subside completely provided the animals are placed on a diet which contains proteins in sufficient amounts. Thirty per cent is to be considered the optimum level of casein. The correction of the anemia manifests itself by a considerable increase in reticulocytes, which usually occurs about the fifth day of the protein regimen and which may be associated with a normoblastic discharge and the sudden occurrence of global leukocytes. The administration of liver extracts alone proved ineffective in anemia due to protein deficiency. The combined administration of casein and liver extracts, and particularly the parenteral administration of liver extracts for several days before that of casein, caused an increase in weight which was particularly evident at 7 per cent levels of casein but also occurred at 15 per cent levels although it was less. Hemopoiesis was not observed on a diet containing casein at 15 per cent levels, while the reticulocyte discharge and the synthesis of the hemoglobin were definitely activated at 7 per cent levels of casein. Correction of anemia and of leukopenia may be obtained in the absence of folic acid. The final resumption of weight gaining and hemopoiesis proves that this intestinal synthesis of microbic origin may be reestablished by the continued supply of proteins.

*Clinical Aspect and Differential Diagnosis of Broncnial Adenoma. A. Kappert.—p. 26.

Bronchial Adenoma.--Kappert reports 3 cases of bronchial adenoma in 1 woman aged 53 and in 2 men aged 27 and 21, respectively. Three stages of the disease may be recognized. Hemoptysis is the most important symptom of the first stage. Recurrent pleuropulmonary disturbances resulting from bronchial stenosis characterize the second stage, and exudative pleurisy may often be responsible for an erroneous diagnosis of tuberculosis. Suppurative complications such as pulmonary abscess, gangrene, bronchiectasis and empyema may occur in the third stage. Diagnosis of bronchial adenoma will best be made with the aid of bronchoscopy. Surgical treatment is indicated. As a rule, endobronchial removal of the tumor should be done first. Improvement in the clinical aspect may often result from the partial removal of the tumor for microscopic examination, but removal of the entire tumor must be the aim of the final endobronchial intervention. Lobectomy and pneumonectomy may be required in cases in which endobronchial removal of the tumor is not feasible or is contraindicated. The author's first patient presented the second stage of the disease and recovery resulted from endobronchial removal of the tumor. In the second patient the correct diagnosis was made with the aid of bronchoscopy during the third stage when a pulmonary abscess was present. Treatment with penicillin was instituted; temperature was restored to normal and the pus was expectorated. Closure of the bronchus by the adenoma may be considered as a protection against new inflammatory bouts. Complete endobronchial removal of the tumor was not feasible in the third patient, who presented a pulmonary abscess and empyema of the pleura complicating the third stage of the disease. Recovery resulted from lobectomy.

Protrusio Acetabuli (Otto-Chroback Pelvis). K. Nievergelt.—p. 31.

Treatment of Fracture of Shafts of Forearm. K. Lenggenhager.—p. 25.

*Tonsillectomy in Carriers of Diphtheria Bacilli. K. Graf. -p. 75.

Tonsillectomy in Carriers of Diphtheria Bacilli.--Graf stresses that in evaluating methods for the eradication of the carrier state in diphtheria it should always be considered that up to the eighth week after the attack the bacilli disappear spontaneously in the majority of cases and the term carrier is justified only for those who retain the bacilli longer. In such case pathologic processes generally exist in the mouth or nose. Chronically inflamed or hyperplastic pharyngeal and palatine tonsils play an important part, since there bacilli find breeding places, which are not reached by disinfection of the surface. Tonsillectomy and if necessary adenotomy usually counteract the carrier state, but remnants of adenoids and tonsils may result in failure. Ozena likewise may nullify the results of tonsillectomy, since the bacilli may continue to grow under the crusts and on the impaired mucosa. If the general condition is impaired, if patients are afraid, or the tonsils are not definitely implicated, an intervention should not be made before the eighth week has elapsed and efforts should first be made to obtain cure by conservative methods such as treatment with artificial fever or with penicillin. The latter can be applied either by injection, locally, by nasal inhalation or spray. If there is a history of repeated attacks of tonsillitis, or of peritonsillar abscesses, and if the tonsils are definitely diseased and the adenoids decidedly hypertrophied, the operation may be performed during the third or fourth week.

Book Notices

Advances in Military Medicine Made by American Investigators Working Under the Sponsorship of the Committee on Medical Research. Edited by E. C. Andrus and others. Associate editor: Tuckerman Day. Foreword by Alfred N. Richards. No. 4 , Science in World War II, Office of Scientific Research and Development. In two volumes, Cloth. Price, $12.50. Pp. 472, with 62 illustrations; 473-900, with 63-94 illustrations. An Atlantic Monthly Press Book. Little, Brown & Co., 34 Beacon St., Boston 6, 1948.

These two volumes comprise a record of results of the great cooperative effort in medical research conducted in the interests of national defense by the Office of Scientific Research and Development during World War II. The record is necessarily incomplete and lacking in technical detail. The definitive records can be found in medical and scientific journals and monographs in which more than 1,300 papers have been published and in which hundreds more will appear. In the foreword Dr. Alfred N. Richards, chairman of the Committee on Medical Research, outlines the organization and administration of that Committee, which President Roosevelt established by executive order on June 28, 1941. The Committee on Medical Research was a constituent agency of the Office of Scientific Research and Development, and it obtained vital assistance from the division of medical sciences of the National Research Council. The Committee on Medical Research by 1943 had fifty-two committees with a total membership of 297; in addition it had liaison with the armed services and many other groups. The Committee on Medical Research was legally empowered to recommend the expenditure of government funds, which the National Research Council, not being a government agency, could not do, and thus to finance numerous scientific projects. The National Research Council considered 951 proposals for research, of which 638 were approved and transmitted to the Committee on Medical Research; of these, 501 became the basis of contracts for investigations. In addition, 90 proposals were recommended and approved by the director of the Office of Scientific Research and Development without prior consideration by the National Research Council's Committees. The contracts thus entered into involved one hundred and thirty-five universities, hospitals, research institutes and industrial firms, and the sums expended on these researches amounted to about $25,000,000.

In these two volumes the fields of research involved in this great undertaking are discussed. The reports already published are tabulated, as are the subjects of the numerous contracts. Dr. Richards points out that in most cases financial loss to the nonprofit institutions was avoided. However, there can be no question, he said, of the strain put on many of the investigators who were obliged to carry on their teaching duties at an accelerated tempo at the same time.

Following the Normandy invasion in 1944, the director of the Office of Scientific Research and Development began planning to terminate its activities, and from the beginning of 1945 the Committee on Medical Research was not encouraged to make new commitments other than those of short range and practical usefulness. The military services were then given the opportunity to take over under their own contracts any investigations that were of special interest to them, and about one hundred contracts were transferred.

A partial list of subjects discussed in these volumes includes blood substitutes, the history of plasma fractionation, burns, tropical diseases, shock, motion sickness, crash injuries, wound ballistics, insecticides, insect repellents, DDT, antimalarial drugs, the development of penicillin, nutrition, chemical warfare agents and acclimatization to hot and cold. An extensive bibliography and index are included.

Animal Genetics and Medicine. By Hans Grüneberg, Ph.D., M.D. With a foreword by Sir Henry Dale, O.M., G.B.E., F.R.S. Cloth. Price, $5.50. Pp. 296, with 33 illustrations. Paul B. Hoeber, Inc., 49 E. 33rd St., New York 16, 1947.

The author has carried on extensive research on the role of hereditary factors in the development of laboratory rodents, especially the mouse. He previously published a book entitled "The Genetics of the Mouse." He has, in addition, a long list of papers to his credit which deal primarily with new mutation or inherited variations in the laboratory mouse. He may therefore be considered well grounded in the subject which he develops. The last short paragraph of the book reads as follows: "The study of inherited diseases in animals is a new branch of medical science. If this book will convince a few people of the value of this new tool for aetiological studies it will have fulfilled its purpose." This paragraph states in essence the content and purpose of the book.

After three introductory chapters on general principles, the author devotes six chapters to a discussion of inherited variations of the central nervous system as shown by studies on laboratory rodents The specific topics of these six chapters include: pseudencephaly, encephalocele and spina bifida, syringomyelia, corpus callosum, otocephaly, hydrocephaly, spastic spinal paralysis, shaking paralysis, ataxia, epilepsy and audiogenic seizures. Brief attempts are made to relate these to similar affections in the human being. The next twelve chapters concern the ear, eye, endocrine organs, blood, skeleton, digestive system, urogenital system and the skin. Chapter XXIII deals with the subject of serology as it pertains to the laboratory rodent. The K and H systems in the rabbit are discussed as is the inheritance of the capacity to develop anti-M and anti-N serums by rabbits. Short paragraphs deal with xanthine oxidases and esterases in mice. In the chapter on Disease Resistance the author discusses briefly the inheritence of resistance to bacterial toxins, bactericidal powers of the blood, leukocyte levels and resistance, and organ response to resistance. He closes this chapter with the statement "It will be obvious to the reader of this book that results of this general kind are the real essence of research into disease resistance ....It does not appear unduly sanguine to hope that the results obtained in animals may, in some cases at least, be found applicable in human beings. For a relation, once critically demonstrated in animal material, should be verifiable in many cases even in the subject of casual and formal genesis of diseases."

In the introductory chapters the author discusses man. He calls attention especially to an apparently common point of view among investigators, namely, that a disease with a hereditary basis belongs in a mysterious category of diseases which do not lend themselves to exploration. He emphasizes properly, as many geneticists have previously, that genes act only through physiologic channels and that their actions are as subject to investigation as are the effects of bacteria or any other causal factor. Objections could be raised to some of the author's opinions regarding a few general questions, but these objections are minor. The book is a laudable attempt to call to the attention of the medical investigator some of the information that is available regarding the inheritance of diseases among laboratory mammals. The book is written in a nontechnical style and should be understandable to anyone with a general biologic background. It may be recommended highly to medical investigators, and even to general medical practitioners.

Neurological Complications After Spinal Anesthesia and Results, from 2493 Follow-up Cases. By Gunnar Thorsen. Translated by Ulla Schott. Acta chirurgica Scandinavica. Vol. XCV, Suppl. 121. Paper. Price, 15 kronor. Pp. 272, with 11 illustrations. P.A. Norstedt & Söner, Tryckerigatan 2, Stockholm 2, 1947.

The following quotation from the author's preface and introduction are pertinent!

> When a medical method, whether diagnostic or therapeutic, has been generally recognized it easily becomes a matter of routine, being deprived of unceasing critical observation. Indications and contra-indications become blurred. Results are misjudged. Limitations and risks are forgotten. It therefore becomes imperative to analyze now and again the results arrived at, as well as, the risks and indications of the methods employed....I assumed, to begin with, that these complications (neurological) were rare and, therefore, almost negligible (after spinal anesthesia). I have come to the opposite conclusion.

The author send out 3,335 questionnaires to persons who had received spinal anesthesia at the Central Hospital in Orebro during a period of three years. Replies were received from 2,493 (74.7 per cent). Modified questionnaires were sent to 120 persons who had been subjected to diagnostic lumbar puncture only, and 100 replied. Analyses of these questionnaires form the basis of the monograph. In addition, reports of physical examinations of patients who complained and autopsies of those who died after spinal anesthesia are included, together with case reports from other institutions and certain experimental data. An extensive review of the literature accompanies the various sections of the monograph. The exhaustive and scholarly classifications of the signs and symptoms encountered is accompanied in each case by logical attempts to explain mechanisms, and these are supported by experimental evidence in many cases. Details of the major discussions cannot be referred to in such a review as this. Causative factors are divided into effects due to (*a*) direct trauma from the puncture needle, (*b*) leakage of spinal fluid, (*c*) infection and (*d*) the anesthetic agent itself. The following quotations are from the author's discussion of the effects of the agent:

> In all the "primary neurogenous" forms the changes of the cerebro-spinal fluid are insignificant or lacking altogether. ...The aseptic meningitis generally sets in on the third to fourth day, often being preceded by prodromes such as headache, etc. It is, as a rule, benign. The arachnitis is characterized by a free interval of days or years between the spa (spinal anesthesia) and the onset of the symptoms....Their occurrence is far more common than is generally thought and the number of the true injuries may be estimated in the present material at a minimum of 1/200. Symptoms, such as a feeling of weakness in the legs, have however been reported in 7.0 per cent and numbness in the legs in 13.3 per cent in the questionnaire material. ...Injuries to the nervous substance and membranes are highly dependent on the concentration of the anaesthetic solution. They are equally common after novocaine (procaine) and percaine (dibucaine) anaesthesia. The weakest possible solutions should, therefore, be chosen with due regard to isotonia and reaction.

A brief review of this valuable and informative piece of work cannot do it justice. It deserves careful reading and consideration by every anesthetist and every surgeon, whatever may be the technic which they use. Perhaps there may be stimulated, as a result, a series of similar thorough studies in this country, with a corresponding awakening to the imperfections of our results. The work seems to suffer considerably in arrangement and in translation. It is, however, an outstanding contribution to the literature of spinal anesthesia.

Die Skelettvarietäten des Fusses: Ihre klinische und unfallmedizinische Bedeutung. Von Dr. Theo Marti, Spezialarzt für Chirurgie F.M.H., Kreisarzt der Schweizerischen Unfallversicherungsanstalt an der Hauptagentur in Genf. Heft 2, Praktische Beiträge zur Orthopädie, herausgegeben von Prof. Dr. Hans Debrunner und Prof. Dr. Max R. Francillon. Paper. Price, 14.20 Swiss francs. Pp. 164, with 58 illustrations. Hans Huber, Marktgasse 9, Bern 16, 1947.

The author's observations are based on many months of experience in the hospital of the Swiss Traumatic Surgical Insurance Association. Variations from the normal forms of the skeletal system are not unusual in the hands and feet. They occur as supernumerary elements or as fusions of normally independent skeletal segments. Other varieties occur in relation to form, size and type of individual bones, either by partial malformations or by variations in normal positions.

The interpretation of roentgenograms with accessory bone elements following trauma may be difficult. These elements may be mistaken for fractures or arthritic changes. Likewise, the reverse may be true. When judging traumatic surgical cases, a mistake may have serious financial and social consequences. For that reason, correct differential diagnosis is necessary. The complexity of the problem is well known. While these varieties were considered at one time to be "sports of nature," there may be a connection, for example, between the accessory tarsal segments and arthritis deformans. Static complaints on the part of the patient may produce localized symptoms. Some accessory bones have a close relationship to deformities of the foot. The presence of accessory tarsal bones favors distortions.

The accessory skeletal elements themselves may be subjected to pathologic changes or may be the sites of isolated traumatic injuries. The knowledge of these changes is important from a therapeutic point of view, but also in determinations of traumatic medical judgment.

The complex problems of accessory tarsal elements are discussed, and literature on the subject is evaluated. Most of the reports in the literature are on a case history basis. They are described here in three sections. The first section describes the problem of foot variations in general, based on anatomic, morphologic, static and roentgenologic descriptions in the literature. The second section concerns the well known variations; the accessory tarsal elements and synostoses are described in detail and reference is given to our knowledge of changes and anomalies of sesamoid bones. In the third section, the author analyzes foot variations in relation to legislation in the Swiss traumatic surgical laws.

Traccion esqueletica. Por Carlos E. Ottolenghi, profesor adjunto de ortopedia, Buenos Aires. Fabrikoid. Pp. 733, with 672 illustrations. Libreria y editorial "El Ateneo," Florida, 340--Cordoba, 2099, Buenos Aires, 1946.

This monograph is a historic document of keen interest to students and practitioners alike. Unfortunately, it is not available in English. The author's qualifications are excellent, and he is well known to orthopedic surgeons, particularly in this hemisphere. The book fills a need. The contribution is of the highest quality. Although it may be criticized for being too comprehensive, it is an excellent reference book. This profusely illustrated work is a comprehensive study of skeletal traction. The historical background, including the controversy on priority, is given as far back as Codivilla and Steinmann.

The evolution of the method is carefully presented, emphasizing the necessity for special equipment. Ottolenghi summarizes his long experience and the mechanical investigations which he has pursued regarding the instruments he considers best, including a stirrup of his own design. The reaction of soft tissues and bones around pins and wires was studied from the clinical point of view and supplemented by experimental work on dogs and rabbits. A specially trained hospital staff is an important factor in obtaining excellent results. Use by inexpert operators is the cause of many failures. These failures are due to errors in technic.

There are two dangers inherent in the method: infection and the possible delay in consolidation. The first is easily avoided if all the prerequisites of asepsis and antisepsis are maintained. Delay in consolidation is due to the use of excessive traction. The importance of repeated roentgenographic control is emphasized. Continuous traction for a prolonged period preventing contact of the fragments will bring about the formation of fibrous tissue. Proper traction avoids secondary displacement and aids consolidation, because the forces of concentric pressure which act on the area bring about the formation of bone callus. The author maintains that skeletal traction applied with correct technic and precise indications is perfectly tolerated. Many interesting technical problems are referred to in the special section where all technics are analyzed and end results are shown. Ottolenghi believes that recent advances in the treatment of fractures will lessen the indications for skeletal traction. The book is accurately documented and a large bibliography is appended.

The Problem of Cerebral Palsy Today. By M. A. Perlstein, M.D. Prepared with the assistance of William McPeak. Paper. Pp. 57, with illustrations. Distributed by the National Society for Crippled Children and Adults, 11 S. La Salle St., Chicago; Published by Association for the Aid of Crippled Children. 580 Fifth Ave., New York, 1947.

In this paper-bound brochure are assembled the facts about crippling due to cerebral palsy Reasons for neglect of the palsied are: (1) ignorance that they can be helped on the part of (*a*) the physicians, (*b*) the patients and their families and (*c*) society as a whole; (2) the belief that all palsied persons are mentally defective; (3) superstition, (4) the idea that the palsy is a manifestation of some family taint; (5) the broken family situations, usually with child rejection; (6) the expense of treatment; (7) the lack of facilities for treatment; (8) the lack of an emotional appeal to the layman corresponding to that of an acute epidemic disease like poliomyelitis or smallpox, and (9) the philosophy that "only the fit should survive." This should be a valuable booklet for teachers and parents and should not be neglected by physicians. While it is not expected that physicians will personally supervise the details of care and particularly the education of the spastic person, it is of utmost importance that they understand and make the best possible use of their co-workers in the care of the spastic child, namely, the teacher and the parent. All educators should be familiar with the problems involved. This little booklet is an excellent summarization of what they need to know.

A Text-Book of Gynaecology for Students and Practitioners. By James Young, D.S.O., M.D., F.R.C.S.E., Professor of Obstetrics and Gynaecology, University of London, London. Seventh edition. Cloth. Price, $7.50. Pp. 471, with 277 illustrations. The Macmillan Company, 60 Fifth Ave., New York 11; Adam & Charles Black, 4, 5, & 6 Soho Sq., London, W. 1., 1947.

In the seventh edition of this popular book changes were made particularly in the chapters on sex endocrinology, menstrual disorders, sterility, leukorrhea, pain and backache.

In the endocrine therapy of dysmenorrhea, Young prescribes 9.5 mg. diethylstilbestrol daily for the ten days before the onset of menstruation. Nearly all American Gynecologists who prescribe this drug for the relief of painful menstruation tell their patients to take the tablets for fifteen or twenty days beginning shortly after the onset of bleeding. The theory is that such medication inhibits ovulation and thereby relieves pain at the next menses. How the administration of diethylstibestrol during the last ten days controls dysmenorrhea is not clear. In the chapter on leukorrhea there is no mention of moniliasis. In fact, the only discussion of this condition is in the chapter on inflammation of the vulva and vagina, where the word thrush is used. There is one illustration of monilia vulvitis in a case of diabetes mellitus. Monilia infection is encountered frequently enough to warrent at least a paragraph on the symptomatology, diagnosis and treatment.

The use of the roentgen ray is recommended for leukoplakia vulvae where estrogens fail, but roentgen therapy seldom improves this condition. Also, it must be emphasized that estrogen therapy should not be continued for too long because cancer develops in a high percentage of cases of leukoplakia vulvae.

In cases of vaginal inflammation the author still finds tampons soaked in ichthammol in glycerin useful. He believes that the cervix can be a focus of serious infection. He relieves pains of the iliac fossa by injecting 85 per cent alchol or "proctocaine" into the Frankenhauser sympathetic plexus.

The section on special tumors of the ovary is excellent and ample. Only thirty-two pages are devoted to operative gynecology. This section should be either enlarged considerably or omitted entirely.

The book is well written and abundantly illustrated. However, seven illustrations are used in two different sections (figures 103, 113, 120, 121, 122, 136 and 236). In spite of the foregoing criticisms, the book will prove to be most useful to students and practitioners because it contains sound advice on all gynecologic problems. This is to be expected, because Young is one of the foremost gynecologists in the world.

A Text-Book of *Bacteriology. By R.W. Fairbrother*, M.D., D. Sc. F. R.C.P., Director of the Department of Clinical Pathology, Manchester Royal Infirmary, Manchester, England. Fifth edition. Fabrikoid. Price $6. Pp. 480, with 6 plates. Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1948.

The fifth edition of this book was issued in September 1946 and reprinted in the United States in January 1948. The book is an outline of the medical aspects of bacteriology and therefore is not documented with references to the original literature. Obsolete material has been removed and an attempt made to bring the subject material up to date. Although a section on penicillin is included, no mention is made of streptomycin or other antibiotics. This may be explained on the basis of the revision date. This book should save much time for the medical student by avoiding controversial issues and presenting only the essential facts in the field of medical bacteriology.

Case Histories in Clinical and Abnormal Psychology. Edited by Arthur Burton, Associate Professor of Psychology, Willamette University, Salem, Ore., and Robert E. Harris, Associate Professor of Medical Psychology, University of California, San Francisco. Cloth. Price, $4. Pp. 680, with illustrations. Harper & Brothers, 49 E. 33d St., New York 16, 1947.

This multiple authored book contains case histories of a wide variety of psychologic disorders written by forty-one psychologists and four psychiatrists. The editors state that their purpose has been twofold: "first, to present examples of most of the personality and behavior disorders; and second, to exhibit the work of competent clinician". The medical reader may think that "clinican" means a psychologist working in his traditional functions of diagnostic testing with patients, but he will find that a psychologist as a clinician is a psychotherapist. Several case histories indicate the therapeutic role of the psychologist and one of them, entitled "Nondirective Counseling," demonstrates the "echo" technic of that school. An introduction by Henry A. Murray covers twenty pages and demonstrates his erudition by rambling somewhat incoherently through a discussion of many distantly related facts. When he comes down to a real introduction, Murray indicates the essential criticisms of this work. Some case histories contain too few important facts and are more descriptive than interpretive. Important dynamic material is not at hand to give awareness of unconscious needs and frustrations. However, the case histories are well chosen to indicate the significance of many important tests in the overall diagnosis and therapy of the mentally ill.

History of Medicine: A Correlative Text, Arranged According to Subjects. By Cecilia C. Mettler, A.B., Ed.B., A.M. Edited by Fred A. Mettler, A.M., M.D., Ph.D., Associate Professor of Anatomy, College of Physicians and Surgeons, Columbia University, New York. Fabrikoid. Price, $8.50. Pp. 1215, with 16 illustrations. The Blakiston Co., 1012 Walnut St., Philadelphia 5, 1947.

Dr. Mettler emphasizes as the purpose of this book the providing of a sense of perspective in facilitating the study of the history of medicine, emphasizing the fundamental value of important medical principles and establishing a feeling of proportion among the component fields of medicine. The student is supplied with an introduction to the principles underlying the development of the various fields embraced in the medical curriculum and an opportunity to become familiar with men who have contributed outstandingly to the progress of the medical sciences. The text is divided into chapters containing the history of a particular subject,with the idea that history of each subject may be studied concurrently with the present day texts. While for these purposes the book will undoubtedly be valuable to the student, as history it lacks unity of presentation of period and integration philosophically with the changing culture of the times . The author has been so precise in attempting to give due credit to the many individual names significant in the historical development of the several branches of medicine that the reading frequently becomes dull. Nevertheless, this same emphasis makes the book excellent for reference.

In many medical schools, after a preliminary period of enthusiastic acceptance of the teaching of the history of medicine, a failure to continue occurs, attributable to lack of systematization. With this in mind, the author has attempted an objective presentation of the verifiable facts from the time of primitive man through the nineteenth century, dividing the history into fifteen sections, including anatomy, physiology, pathology, bacteriology and the several specialties. For teaching the history of medicine in medical school the volume will find considerable acceptance and additionally will serve as an excellent reference to persons prominent in the development of medicine from early times.

New Fields of Psychiatry. By David M. Levy, M.D., Assistant Professor of Psychiatry, College of Physicians and Surgeons, Columbia University, New York. Cloth. Price, $2.75. Pp. 169. W. W. Norton & Co., Inc., 101 Fifth Ave., New York 3, 1947.

This is a brief, personal, interesting and authentic account of psychiatry as it finds application in diverse fields of human affairs. The author has been identified with the development of psychiatry in child guidance and in the field of delinquency. This in turn has involved him in the developing relationship of psychiatry to the field of social work: here he has personally made important contributions (not discussed in this volume) through his teaching and research in psychotherapy. During World War II as psychiatric consultant in the Office of Strategic Services he contributed to the task of personnel selection. Later activity with the screening center of the information control division in the United States zone in Germany brought experience in political psychiatry. Here ascertaining the reliability of Germans who would be in influential political or educational positions was a central consideration; the author also directed himself to the ascertainment of specific psychologically significant differences between Nazi and non-Nazi. This is an excellently written work that is intended to expose the broader aspects of the author's personal experience, with particular emphasis on the development of psychiatry in fields outside of but related to medicine. It should be read by every medical student and psychiatrist; a perspective about psychiatry otherwise quite difficult to achieve can be gained.

Family Skeletons. By David D. Whitney, Professor of Zoology, University of Nebraska, Lincoln. Cloth. Price, $4. Pp. 284, with 246 illustrations. University of Nebraska Press, Lincoln, 1946

This book is one of a series intended to popularize science, and the hope is expressed that this particular volume may "assuage fears and anguish over deformities." It consists largely of illustrations: the explanatory text is brief. An interesting series of pictures of twins, triplets, quadruplets and quintuplets is presented with explanation of the embryologic processes producing them. That is followed by illustrations of abnormalities, natural or artificial, which the author has found either in nature or in the literature. An estimate is given as to whether or not they are hereditary and, if they are, whether inheritance is dominant or recessive and whether of high or low "penetrance" (frequency). A general glossary of terms commonly used in the literature of human heredity is accompanied by a thirty page list (with definitions) of inherited abnormalities and diseases. Some of the illustrations may disturb rather than comfort the minds of the public, even though the conditions said to be inherited are, not all dominant or of high frequency. A little more care by the author or publisher might have prevented some errors. Flexed fingers are said to be due to shortness of extensor tendons, page 106. Hallus (sic) valgus is said to be inherited and dominant, but the illustrations suggest bad shoes and bunions, page 113. Peroneal atrophy is illustrated with legs and hands affected (sic), page 179. "A few persons can move the skin on their forehead" (sic), page 223. "Vitamin C prevents pellagra," page 239.

Surgery: A Textbook for Students. By Charles Aubrey Pannett, B. Sc., M.D., F.R.C.S., Professor of Surgery, University of London, London, England. Second edition. Cloth. Price, 27s. 5d. Pp. 757 with illustrations. Hodder and Stoughton, Ltd. Warwick Square, London, E. C. 4, 1947.

In the author's preface, he cites the need for the student to "get his relative values right." This book includes the usual chapters on diseases of the abdominal organs, head injuries, diseases of the bone, etc. However, chapters on gynecology, ear, nose and throat, bacteriology and pathology have been purposely left out by the author, who feels that these subjects rightly belong to those who teach them.

The text is easy to read; the substance is factual, and presented in a manner devoid of verbiage. The illustrations are extremely diagrammatic, and are used throughout instead of photographs or roentgenograms. The author feels that the student may grasp the point of the illustration more readily if it is simply presented. He makes the interesting observation that these "mind pictures" are more effectively portrayed with an imperfect technic by a surgeon who understands the problem at hand than by an expert who does not.

The chapter on tissue repair and the healing of wounds is comprehensive and adequate in detail. The chapter on gangrene includes an exposition of the common vascular diseases of the extremities with their management. The book is an excellent source of medical information for the student.

Studies on the Formation of Cellular Substances During Blood Cell Production. By Bo Thorell. Paper. Price, 12s. Pp. 120, with 59 illustrations. Henry Kimpton, 25 Bloomsburg Way, London, W.C. 1; P.A. Norstedt & Soner, Tryckerigatan 2, Stockholm 2, 1947.

During the last two decades, remarkable progress in hematology has been achieved by means of sharper demarcation of the various clinical pictures and by application of dynamic physiologic mechanisms to the interpretation of the presenting symptoms and signs. However, in most of the disorders full comprehension is lacking because the underlying disturbances of cellular metabolism remain an enigma. In this important monograph, Thorell has applied the ingenious technics developed by Caspersson for the study of cellular protein formation to the problems of blood cell production. The complicated microspectrographic methods used in these investigations are described in detail. By comparison of the distribution and concentration of the ribose polynucleotides in the hemopoietic cells with the quantitative cytology of the bone marrow, it could be shown that the new formation of cellular proteins during hemopoiesis takes place at an early stage of development. During this stage, high concentrations of ribose polynucleotides exist in the cytoplasm and nucleolar apparatus. During the maturation phase of the blood cells, the concentrations of the ribose polynucleotides decrease continuously, parallel with a declining growth activity of the cells. This latter activity seems to be regulated by a definite part of the chromatin. Endocellular synthesis of hemoglobin does not start before the ribose polynucleotide metabolism is finished. When the maturation phase is ended, the main synthesis of hemoglobin begins. These metabolic processes also operate in the production of the granulocytes. In leukemia, there exists a measurable hypertrophy of the metabolism of the ribose polynucleotides associated with the new formation of new cellular proteins. In pernicious anemia, the polynucleotide and hemoglobin composition during cell genesis was also found to be definitely abnormal. This study is a stimulating contribution. It will be of particular interest to investigators who realize that the future of biologic research is closely connected with a better understanding of intracellular metabolism.

Letheon: The Cadenced Story of Anesthesia. By Chauncy D. Leake. Paper. Pp. 128. The University of Texas Press. Austin, 1947.

The author suggests that this experiment in cadenced narrative of the story of anesthesia should be read aloud or not at all. The author has read it aloud to several medical assemblages, and its reception caused him to make it generally available. The story is supplemented by a chronology of anesthesia and a fine bibliography and index, which make it the kind of book one expects from Chauncey D. Leake. Except for a slight unevenness the work holds the attention, but the story is so condensed that rereading is frequently required for comprehension. Here is a sample in which the author relates a well known anecdote:

> Obstetrics grew with Simpson's chloroform.
> Amusing to us now, he drew upon himself
> the wrath of clergymen, who thundered that
> he dared attempt relief of pain
> in child birth as decreed by God
> But he prevailed by silly argument
> that God Himself approved of anesthesia,
> since He had set the precedent by giving
> sleep to Adam at the birth of Eve.
> When later he was knighted, friends proposed
> a coat of arms, a naked babe, with motto,
> "Does your mother know you're out?"

The Doctor in Oregon: A Medical History. By O. Larsell, Professor of Anatomy, University of Oregon Medical School, Portland. Cloth. Price, $10. Pp. 671, with illustrations. Published for the Oregon Historical Society by Binfords & Mort, 108 N. W. Ninth Ave., Portland 9, 1947.

The earliest doctors came to the Pacific Northwest with the explorers and fur traders. They were truly pioneers. In 1923 Dr. Olaf Larsell, professor of anatomy at the University of Oregon Medical School, initiated a medical history club of the Medical School of the University of Oregon. From this nucleus came a survey of the growth of medicine in Oregon and in the Northwest which makes this history one of the most adequate and competent in the field of the history of medicine as it covers various portions of the United States. Here is the detailed story of the medical missionaries, including the fascinating account of the Whitman Mission, already available in other published works. The biographies of individual physicians who participated in the care of the sick in the Northwest, the developments in public health and in medical science, the regulation of medical practice and the epidemiology are all fully covered in this amazing compilation of material. If there is any single criticism it is the lack of typographic variety and the somewhat congested manner of presentation.

Atlas of Bacteriology. By R. Cranston Low, M.D., F.R.C.P.E., F.R.S.E., Bacteriology Department, University of Edinburgh, Edinburgh, Scotland, and T. C. Dodds, F.I.M.L.T., F.I.B.P., F.R.P.S., Laboratory Supervisor to the Department of Pathology, University of Edinburgh. Cloth. Price, $8.50. 168 plates. Williams & Wilkins Co., Mount Royal and Guilford Aves., Baltimore 2. 1947.

This atlas is for the medical undergraduate who can compare its color photographs with what he sees under the microscope. The plates show clinical material such as pus, urine, blood and sputum with the organisms, the culture films stained, the tissues with the organism in situ and, finally, cultures on various mediums.

Medicine for Moderns: The New Science of Psychosomatic Medicine. By Frank G. Slaughter, M.D. Cloth. Price, $3.50. Pp. 246. Julian Messner, Inc., 8 W. 40th St., New York 18, 1947.

Psychosomatic medicine is the catchword of the hour, and Dr. Frank Slaughter has written about it for persons generally. While not himself especially trained in the field, he has read the best available literature, and his book is essentially a translation of the available writings into everyday English. Yet comprehension may still be difficult for those without some college background in modern psychology and even psychiatry. Dr. Slaughter has been unable to avoid the diction of this new field, and such expressions as "genitalization of the libido" and "id" and "superego" complicate the text. For the unenlightened the explanations do not quite explain. About the best of the chapters is that called "The Discontented Colon." In view of the various organic changes that have been proclaimed in fibrositis, the author seems to overemphasize its psychosomatic origin. Thus far the available evidence does not explain many of the clinical manifestations of fibrositis. Perhaps psychosomatic medicine is not yet ready for dispensing to an unaware public. The conclusion that psychosomatic medicine is the "penicillin" for emotional discord is somewhat too broad a claim.

American Medical Research Past and Present. By Richard H. Shryock, Ph.D., Professor of History and Lecturer in Medical History, University of Pennsylvania, Philadelphia. Studies of the New York Academy of Medicine, Committee on Medicine and the Changing Order. Cloth. Price, $2.50. Pp. 350. The Commonwealth Fund, 41 E. 57th St., New York 22, Oxford University Press, Amen House, Warwick Sq., London, E. C. 4, England, 1947.

Dr. Shryock traces the historical development of medical research in the United States from European sources to the cultural independence that developed after 1895. The outstanding leadership of William Welch is recognized, and the appreciation and growth of private support are adequately recorded. After a chapter on public relations the growth of public support is described, including the work of the National Research Council and the great voluntary agencies. Dr. Shryock concludes that far more support of basic research is needed than has thus far been available, particularly because medical research makes progress chiefly on basic research. He supports the view that there should be governmental support of the social sciences, yet apparently fails to realize the possible menace in political application of social science research.

Brain and Intelligence: A Quantitative Study of the Frontal Lobes. By Ward C. Halstead. Cloth. Price, $6. Pp. 206, with 27 illustrations. University of Chicago Press, 5750 Ellis Ave., Chicago 37, 1947.

Within the narrow limits of two hundred and six pages, Dr. Halstead has compressed a report of twelve years of investigation of the relation between lesions of the brain and "biological" intelligence, which he feels is superior to psychometric, clinical and neurologic concepts of intelligence. Through intensive testing of 237 patients, and through factorial analysis of his results with twenty-seven tests (many of them devised by him for this purpose), he finds "biological" intelligence to consist of four factors: the central integrative field factor, *C*; the abstraction factor, *A*; the power factor, *P*, and the directional factor, *D*. These are measurably reduced through extirpation of cerebral tissue, and this reduction is expressed in quantitative terms as an impairment index. Part II discusses localization of function in the cerebrum through an analysis of the degree of impairment found after lobectomies in the several lobes, the greatest degree being found in the frontal lobes. The appendixes include abstracts of medical histories, diagrams of cerebral lesions, brief descriptions of tests, numerous tables and an extensive bibliography.

All readers must be impressed by the painstaking scholarship shown in the study, and by the ingenuity of the technics developed, but a few may be left with some disturbing questions: (1) Has more attention perhaps been paid to the tests than to the persons tested? (2) Can more be derived from a factorial analysis than is put into it in the first place? (3) Since the neuropsychiatric patients showed an impairment index as great before lobotomy as after it, wherein lies the unique character of "biological" intelligence?

Surgical Disorders of the Chest: Diagnosis and Treatment. By J. K. Donaldson, B.S., M.D., F.A.C.S., Professor of Surgery and in Charge of Thoracic Surgery, University of Arkansas School of Medicine, Little Rock, Ark. Second edition. Cloth. Price, $8.50. Pp. 485, with 148 illustrations. Lea & Febiger, 600 S. Washington Square, Philadelphia 6, 1947.

Dr. Donaldson has attempted to compress into four hundred and seventy pages an up-to-date presentation of the various aspects of surgical diseases of the chest. His principal objective is to supply a relatively brief and readable summary of the manifold developments in the fields of thoracic surgery so that the general practitioner and general surgeon reading the book can be kept abreast of the possibilities of thoracic surgery. The first part deals with inflammations and tumors and congenital anomalies of the thoracic wall and thoracic injuries; the second part with nontuberculous intrathoracic infection, pulmonary embolism and infarction as as well as intrathoracic tumors and congenital abnormalities; the third part deals with the surgical therapy of tuberculosis. The book is abundantly illustrated, and for those who wish to study further in any of the fields covered there is a good bibliography at the close of each chapter. In this edition the author has included a section on the advances which have come out of World War II in the treatment of traumatic lesions of the chest and their sequelae, notably, decortication of the lung. A new section has been added on antibiotic therapy, technics of anesthesia of thoracic surgery, artificial respiration, inhalation therapy and cardiac resuscitation. Advances in the field of esophageal and cardiac surgery have also been included. Clarity would have been better served at times if obsolete and unproved methods were not reported and emphasis applied to well proved methods. Insufficient space was given to the subject of pulmonary resection for tuberculosis and the indications for resorting to resection in abscess of the lung. The book is a useful adjunct to the library of the house officers, general practitioners and general surgeons for whom it was intended.

The World Within: Fiction Illuminating Neuroses of Our Time. Edited by Mary Louise Aswell. With an introduction and analyses by Frederic Wertham, M.D. Cloth. Price, $3.75. Pp. 376. Whittlesey House, McGraw-Hill Book Co., 330 W. 42d St., New York 18, 1947.

From the fiction of the world the author has chosen illuminating portions which describe neuroses as observed by competent writers of fiction. To each section there is an introduction by Frederic Wertham, representing essentially an analysis from the point of view of modern psychiatry. For both the amateur and the professional in the field of psychiatry this is a fascinating work.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST

RH SENSITIZATION

To the Editor:—A 26 year old woman, married for the second time, has a daughter 6 years old. Complications of a first pregnancy were absent. Four years ago last June she delivered a stillborn infant. At that time she found out that she was Rh negative and was told that was the reason that the baby died. Her first husband was not tested. Her second husband is Rh negative (tested at two laboratories), but last August she lost a baby after a six and one-half month pregnancy. It had been dead nine weeks before she delivered it. Could this be due to the Rh factor if both the patient and her second husband are Rh negative They are anxious to have children

Ethel M. Walker, M.D., Ardmore, Okla.

ANSWER.—The clinical story, namely, the birth of a normal child followed by two stillbirths, is compatible with the diagnosis of Rh sensitization as the cause of the stillbirths, and this is further supported by the statement that the patient is Rh negative. However, this interpretation is contradicted by the report that the second husband is Rh negative, considering that two Rh-negative parents can have only Rh-negative fetuses, and Rh antibodies cannot harm an Rh-negative fetus. Unfortunately, errors in Rh testing are notoriously frequent even in laboratories of reputable hospitals, due to the delicate nature of the tests. Unless the tests have been done by one of the central laboratories specializing in Rh testing, the report must therefore be taken with a grain of salt. It is significant that no mention is made whether the patient's serum contained Rh antibodies, and tests for Rh sensitization are essential before a reliable opinion can be offered. If the reports that the patient and her second husband are both Rh negative are comfirmed, and no Rh antibodies are demonstrable in the patient's serum, then one can safely assert that the stillbirths were not due to Rh sensitization. The prognosis for future pregnancies would then depend on the etiology of the stillbirths. For example, if the patient has latent diabetes, another stillbirth might possibly be avoided by suitable treatment of the patient during the next pregnancy, while if the stillbirth were due to accidental factors, such as knotting of the cord or abruptio placentae, repetition of such accidents would not be likely to recur in still a third pregnancy. On the other hand, if there has been a laboratory error, so that the second husband is really Rh positive and the stillbirths are due to Rh sensitization, then further studies are necessary to determine, if possible, whether the husband is homozygous or heterozygous and to determine the titer of the Rh antibodies in the patient's serum. With reliable information of this sort, a definite prediction may be possible regarding the probable outcome of subsequent pregnancies.

TRAUMA IN PREGNANCY

To the Editor:—A white woman aged 37 is 53 inches (134.6 cm.) tall and weighs 133 pounds (60.3 Kg.). She has hyperlordosis. She fell down a flight of stairs in March 1945, sustaining injury to her back. At that time history of pregnancy or bleeding was absent. On June 3, 1945, she had a complete abortion which she thought had started in February 1945. In February 1946 she had another spontaneous abortion. On Dec. 29, 1947, she had a hysterectomy because of bleeding, and a diagnosis of myoma of the uterus was made. At that time a left cystic ovary was removed. The microscopic report did not show myoma. Could these miscarriages and apparent functional bleeding be due to the injury she sustained in 1945?

M. D., Connecticut.

ANSWER—A possible connection, scientifically, with the patient's signs and symptoms and the fall and possible injury to the back is not apparent. The abortion occurred when the patient was approximately three to three and one-half months pregnant and at least two months following the injury. A second abortion is even stronger evidence against trauma's producing the abortion.

Traumatic abortions are usually produced by direct trauma against the abdomen and wall of the uterus and may lead to abruptio placentae and abortion.

Another conceivable method of production of traumatic abortion would be trauma severe enough to rupture the corpus luteum of early pregnancy. Trauma of such severity in such a well protected organ seems improbable.

A much more logical point of view would be to assume that this 37 year old woman probably had fibroid tumors for at least two years before operation and that they were more likely the cause of the abortions. Women with fibroids are less likely to get pregnant than others, are more likely to abort and if they carry a baby to visibility or term are more likely to have complications of labor.

From the wording one cannot determine whether the sections reviewed showed myomas or whether there were none present in the uterus as a whole.

With uterine fibroids, Dr. Arthur Curtis has called attention to so-called oyster ovaries, slightly enlarged and soft.

With cystic glandular hyperplasia of the endometrium or so-called swiss cheese endometrium, the ovaries may contain atretic follicle cysts. However, this type of endometrium usually shows no secretory or progestational phase and therefore the patient probably does not ovulate and therefore probably would not get pregnant In this case, the operation followed the last pregnancy by nearly two years, and therefore cause and effect relationships are only theoretical.

ELECTRICAL RESISTANCE OF BODY

To the Editor:--In volume I of "Legal Medicine and Toxicology" by Peterson, Haines and Webster, second edition, page 264, the following statement is made relative to electrical resistance between the two hands of a person. "Herold quotes Bullard's computations on 259 males, where the resistance from one hand to the other varied from 550 to 1,970 ohms, and in a series of measurements of 236 men, also quoted by Herold, the average resistance was 1,184 ohms, the extremes ranging from 610 to 1,870 ohms." These figures are so grossly at variance with a few tests which I have made on my own hands and which have been made for me by various radio men on the ohm meters which are now in common use in radio repair establishments that it is impossible for me to reconcile my figures with those stated in the book, my tests showing ohm values of ten or more times those mentioned. What is your opinion?

Robert B. Taft, M. D., Charleston, S. C.

ANSWER.—In the absence of details as to the tests conducted by the questioner, one can only answer by quoting more extensively from volume I of "Legal Medicine and Toxicology" by Peterson, Haines and Webster, second edition, pages 263 and 264.

Resistance of the Body.--One of the most important safeguards against the passage of electric currents through the human body is its high degree of resistance. This is largely proportionate to the fluid constituents. This is very frequently stated to be from 1,000 to

3,000 ohms, but there are so many circumstances which modify this that didactic statements should not be made without taking these into consideration. Thus, when the epidermis is perfectly dry, its resistance to the passage of electric currents has been shown by Jolly to be very high, measuring, in Siemen's units, from 8,000 to 40,000 ohms (Herold). Dry skins are more resistant, also hard and oily skins. Moist, soft and perspiring skins have much reduced resistance. If the skin is thoroughly moistened, the resistance of the body may register but 500 ohms, and skins treated with alkalis that remove the fat are less resistant. Herold quotes Bullard's computations on 259 males, where the resistance from one hand to the other varied from 550 to 1,970 ohms, and in a series of measurements of 236 men, also quoted by Herold, the average resistance was 1,184 ohms, the extremes ranging from 610 to 1,870 ohms. In addition to this external moisture there may be a number of important factors, pertaining to the internal composition of the tissues through which the currents may pass, which are but little understood.

"ERTRON"

To the Editor:—What is the consensus regarding use of "ertron" in certain or any type of rheumatism?

R. B. McBride, M.D., Dallas, Texas.

Answer.—Treatment of various types of arthritis by the use of concentrated vitamin D, of which "ertron" is an example, was proposed by Dreyer and Reed in 1935. Since then, certain commercial products of concentrated vitamin D have been highly, and sometimes objectionably, publicized, especially for the treatment of rheumatoid arthritis. But after their use in such cases, no significant number of sustained remissions and little or no objective improvement have been noted by the majority of critical investigators, although decrease in pain sometimes has been noted. The value of concentrated vitamin D in the treatment of other articular and rheumatic diseases is even more uncertain. Most experienced rheumatologists now regard these products as essentially useless for any type of arthritis.

The use of concentrated vitamin D is not without danger. Such therapy mobilizes calcium in the body and may lead to its ectopic localization in various parts of the body, notably in joints and in kidneys. Severe renal damage and even death may result. Although untoward reactions are said to result less often from electrically activated vaporized sterol (such as "ertron") than from ultraviolet irradiated ergosterol, severe and sometimes fatal reactions have accompanied the use of "ertron.". "The drug [ertron] is far from being as innocuous as its manufacturers claim" (Kaufman, P.; Beck, R. D., and Wiseman, R. D.: The Journal, p. 688 [June] 1947).

MALE FERTILITY

To the Editor:—1. Is there a relationship between the sperm count and protein levels in the blood? 2. Is there a relationship between the sperm count and age of the subject? 3. Please list a few articles which deal with the sperm counts and male fertility.

M.D., Wisconsin.

ANSWER.—1. Fifteen years ago Meaker and his co-workers showed that protein starvation can be a factor in human male infertility. Their diagnosis of this dietary insufficiency was made, not by direct determination of protein levels in the blood, but indirectly by a quantitative comparison of intake and output of nitrogen. The resulting infertility in such cases is evidenced by a high incidence of abnormal morphology oftener than by a reduction in the sperm count.

Reynolds and Macomber had previously reported the effect of protein deficient diets on the fertility of white rats. Among their experimental animals only 14 per cent of matings were fertile, as compared with 65 per cent among control animals on a normal diet.

2. In general, male fertility tends to decline slowly after middle age. This change may be indicated by lower sperm counts, poorer morphology or a higher incidence of abortions and stillbirths when pregnancies occur. But there is great individual variation. Even in advanced old age many men continue to produce apparently good semen, and some prove to be clinically fertile.

3. The subject of sperm counts and male fertility is adequately covered in the texts of Hotchkiss and of Lane-Roberts and associates. Each of these books gives an extensive bibliography.

MENOPAUSE

To the Editor:—My patient complains solely of her knees- " warm on the outer side, cold on the inner side." This is true on physical examination. Patient is a woman at menopause. She has no other complaints. What is your opinion?

M.D., New York.

ANSWER.—A therapeutic test with estrogens, administered either orally or parenterally, should suffice to determine whether the symptoms are ascribable to the menopause. The dosage should be that commonly given for relief of menopausal symptoms.

HEMOLYZED BLOOD

To the Editor:—Can hemolyzed blood be transfused without regard to its original type? Is it a safe procedure --safety referring to the freed hemoglobin suddenly introduced into the recipient's system? Will hemolysis of the blood destroy its respective agglutinogens, making it thus a solution of foreign protein apt to cause a foreign protein reaction in the recipient's body?

R. J. Kent, M.D., Savannah, N. Y.

ANSWER.—To the best of our knowledge transfusion of hemolyzed blood is practically and theoretically a dangerous procedure. Hemoglobin has been used experimentally as a blood substitute only after freeing the solution of cell stromas. The antigenicity of whole blood is well established, and there is no evidence that hemolysis of the red cell destroys its ability to act as an antigenic agent.

RABIES

To the Editor:—Two months previous to his death, a patient, 45 years of age, was bitten on a finger tip by his dog. The dog died a " few " days after the patient received the injury. The number of days is uncertain, but definitely less than ten. There is no record that the dog had been vaccinated against rabies. His head was examined by the state laboratory which reported that Negri bodies were not found. Intracerebral inoculation with emulsions of the dead dog's brain was not performed. A clinical record of a veterinarian to justify the assumption that the dog did not have rabies is lacking. For lack of certainty, this patient received fourteen injections of phenol-killed rabies virus vaccine. No reactions occurred and the patient was well until six days previous to his death. The onset of the final illness was sudden with severe persistent low retrosternal pain and moderate shock, but without evidence of hyperirritability, spasms or delirium. Serial electrocardiographic tracings showed a progressive, extensive, myocardial infraction involving the septum. There were moderate fever (up to 101F.) extensive myocardial infarction involving the septum. There were moderate fever (up to 101 F.) and leukocytosis. On the fourth day of the illness he became disoriented at times, unable to sleep and gradually so restless that at the end of the fifth day he had to be restrained. In spite of paraldehyd orally and hypodermically, barbiturates by mouth and intravenously, the restlessness did not abate, so that it was deemed advisable to give him " pentothal sodium " as a last resort. The patient died a few minutes after the instillation of tribromoethanol solution with sudden cyanosis and cessation of the heart action. No necropsy was permitted. The question of rabies came up for discussion before death, but in view of the history, the lack of dysphagia and respiratory disturbances, the prophylactic vaccination and the sudden onset with a classical picture of coronary infarction, it was felt that diagnosis of rabies could not be seriously entertained. The method of intracerebral inoculation of mice with penicillin-treated saliva was then not known to us. Unusual precautions to protect the physicians, nurses, or relatives were not taken. The only method of transmission to be considered in this case is the possibility of droplet infection, as he did have a moderate cough. 1. Is it reasonable to rule out rabies altogether? 2. Can the coronary infarction, and especially the terminal irritability, be considered as part of a delayed reaction to vaccine?. 3. Under the circumstances presented, should the attending personnel be vaccinated in spite of the known danger of vaccination? 4. Which vaccine should be preferred, the simple phenol-killed or the ultraviolet-killed virus?.

M.D., Pennsylvania.

ANSWER.—1. No conclusive evidence of rabies is presented in either the dog or the patient.

2. Whether the vaccination played any part in the final illness cannot be determined, but the illness may have occurred independently of the vaccination.

3. There are no indications for antirabic vaccination of the attending personnel. There is no evidence of rabies in the patient, and then rabies is not spread by droplet infection in the usual sense.

DERMATITIS HERPETIFORMIS

To the Editor:—A patient who is known to have diabetes has been taking plain and protamine zinc insulin for seven years, and the disease is well controlled. Approximately three years ago a rash developed on the elbows, knuckles, knees and buttocks. A dermatologist at that time prescribed sulfapyridine. The rash completely disappeared for five months. When it recurred, he was given roentgen therapy and again put on sulfapyridine. Since that time, rash recurs immediately whenever sulfapyridine is withdrawn, and the patient is on a maintenance dose of 5½ tablets of sulfapyridine daily. The rash does not vary in severity with temperature or seasonal changes. At this time, there is seen only a few small dried crusts on the elbows, but when sulfapyridine was withdrawn several days ago, small vesicles appeared within twenty-four hours, with only a mild degree of itching. The patient has no other complaints, and history and physical examination are otherwise negative. Various other sulfonamide drugs and penicillin fail to control the rash.

J. H. Bohnfalk, M.D., San Antonio, Texas.

ANSWER.—The original use of sulfapyridine prescribed by a dermatologist, the disappearance of the eruption following its administration and the presence of vesicles when the eruption recurs suggests diagnosis of dermatitis herpetiformis—Duhring's disease.

For reasons that are not clear the sulfonamide compounds, notably sulfapyridine, may be effective in treatment of dermatitis herpetiformis; continued administration may prevent recurrence of the disease. For some patients the maintenance dose may be as little as 1 or 2 tablets daily or every other day. The drug should be administered with sodium bicarbonate.

Dermatitis herpetiformis frequently occurs in the highly strung overactive "can't relax" type of patient. This has caused speculations on the psychodynamics of the malady. There is no known relation of the disease to diabetes.

Other phases in treatment concern attention to the general state of health; with particular reference to rest, recreation, relaxation and conservation of nervous energy, a strict saltless diet and avoidance of ingestion of the other halogen compounds—iodides and bromides. Exposure to the ultraviolet light to the extent of tanning and injections of the patient's own blood into the buttock are at times helpful. The oral administration of solution of potassium arsenite—Fowler's solution—has long been used in treatment. Too continuous administration, of course, should be avoided. In some patients recurrence of the disease may be prevented by alternating maintenance doses of Fowler's solution and sulfapyridine. Local treatment of dermatitis herpetiformis is discussed in textbooks on diseases of the skin.

ALLERGY FROM SHOES

To the Editor:—I have under my care a patient who presents a chronic papulovesicular eczema of both feet of several years' duration. Secondary fungous involvement has definitely been cleared up. Results of potassium hydroxide tests and culture (Sabouraud's) have been negative for several months. Patch tests to shoe dye and shoe leather have been negative in result, but the eruption clears up on therapy with aluminum acetate solution N.F. and boric acid ointment as soon as he is kept off his feet and prevented from wearing shoes. He has had ample roentgen therapy from previous dermatologists. Can you recommend anything as a protective agent to prevent contact with shoe leather again, or what procedure could be used to protect or substitute for shoe leather? I know of no "synthetically" made shoes, and it will be a problem to put some walking apparel on this man after the eczema clears up.

M.D., Ohio.

ANSWER.—Dermatitis from shoes may occur from materials other than the leather or dye. Shaw (Arch. Dermat. & Syph 49:191 [March] 1943) reported 22 cases of dermatitis due to shoes in which the offending substances were found to be glue, felt, canvas, polish, trimmings, dye, top leather and the lining leather of the shoes.

An effort should be made in this case to determine the offending agent by means of patch tests. In unusual cases such as this, manufacturers are usually willing to cooperate by furnishing the materials for testing. Also, it may be possible for the patient to avoid trouble simply by changing to another brand of shoes. The chemical processes used in the manufacture of shoe materials are numerous and varied, not all shoes being chemically alike. If the patient is bothered by all brands of leather, he could wear shoes made of canvas, and the skin could be protected by the application of a paste such as paste of zinc oxide thinned with a little petrolatum if necessary.

MONGOLIAN IDIOCY

To the Editor:—The wife of a major of this Command gave birth to fraternal male twins in Japan four months and three weeks ago. One weighed 5 pounds 10 ounces (2,552 Gm.) and the other 5 pounds 2 ounces (2,325 Gm.) Up to the time that I first saw them three weeks ago the parents had been told that the children were perfectly normal. Both parents are intelligent. The father is 30 and the mother 28 years of age. Family backgrounds are not unusual. The mother was the seventh child in her family, born when her own mother was 42 years of age. During the year before the last pregnancy with the twins the major's wife had irregular and briefer menstrual periods than at any other time.

Examination of the twins revealed that one weighed almost 18 pounds (8,165 Gm.); he was lethargic and pale; the anterior fontanelle admitted one finger; he had "mongoloid facies"; when he cried after I squeezed his toe hard his face flattened out. The second twin weighed almost 15 pounds (6,804 Gm.), and all other observations were the same as that for the first boy, with the addition of a flat occipital area and a right testicular enlargement, which the parents state is getting smaller. Both boys eat well and do not cry much. Movements of the first child are slower and more "massed" than those of the second; both follow light with their eyes but tire easily; if I clap my hands they blink. Although the parents insist that the infants did not seem alike at birth they appear to be perfect identical twins at present.

I thought that they might be mongolian idiots and sent them to the pediatrician at the nearest Station Hospital. He told the parents that they were idiots, without a possibility of a doubt, and painted the worst possible picture for the future. A blood cholesterol determination on one of the boys gave normal results.

Being without the advantage of a skilled consultant over here, these are my questions: 1. What things can be done when the twins are six to seven months of age to prove definitely whether they are mongolian idiots? If this age is too early, please describe in detail the tests that can be performed and the earliest possible age?

2. If they are mongolian idiots: (*a*) can I reassure the parents that this is something for which neither of them is responsible? (*b*) The parents are anxious to have a normal family but are now extremely fearful lest this might repeat itself. Should they be advised to try again? (*c*) What is the procedure usually advised with regard to placement in an institution? What are the average costs in a state or private

institution and at what age can the children be admitted? The parents are Texans, but, being in the Army, are in travel status. (*d*) If the diagnosis is correct, the parents are willing that medical science observe the boys for research, experimental medicine. The father will even take movies of them at various ages if this would contribute anything. Is there any group who might want to work with them? (*e*) (1) Is there possible benefit from surgical intervention? (2) Can mongolian idiocy be determined before birth?

Captain, M.C., U. S. Army.

Answer.—1. Check the physical findings elicited in a more thorough examination against those listed in any standard textbook of pediatrics—even one in Japanese, with the aid of a translator The physiognomy is so characteristic that "the mongoloid facies" observed by the correspondent could be confirmed by photographs mailed to this country At any Army Command it would also be a simple process to take handprints and footprints, which would be informative.

The distance between the bregma and occiput and the circumference of the skull should be measured for comparison with norms for the age, as brachycephaly is characteristic of mongolism. Abnormal formation of the ear lobes and the presence of congenital heart disease are in favor of the diagnosis Other stigmas at 6 months of age due to generalized neuromuscular hypotonia would be inability to hold the head up, alternating or persistent strabismus and hyperflexibility of joints. No single finding is pathognomonic, but the aggregate syndrome is usually unmistakable. The testicular tumor might be an associated defect such as a hernia or hydrocele.

Roentgen examination of hands may reveal the defective formation of the middle phalanx of the fifth finger—found in about two thirds of mongoloid persons—and anteroposterior views of the skull may reveal the characteristic acromicria. Prints of these plates could easily be made for dispatch to the United States with the photographs and handprints.

2. (*a*) Epidemiologic evidence points toward maternal factors as the cause of mongolism.

(*b*) Multiple instances of mongolism in the same family are so rare as to warrant a "lightning does not strike twice in the same place" attitude toward future progeny. This advice, however, is predicated on a complete check-up of the mother's health with positive measures taken to remedy any chronic, systemic, endocrine or gynecologic disorders found (especially in view of the mother's menstrual history). It is also predicated on the placement of the mentally retarded twins in an institution in order to allow future children normal care in a normal home.

(*c*) The query should be made to the director of a state-maintained institution of Texas.

(*d*) Many large clinics would "want to work with them" However, a vast amount of research has been done on treatment of mongoloid persons without revealing substantial hope for cure Of more promise is evidence that the condition may be prevented, at least in part, by an increased understanding and control of the causative factors and mechanisms operating in early pregnancy.

(*e*) (1) No. (2) Not clinically, occasionally at autopsy.

MEASLES IMMUNE GLOBULIN

To the Editor:—Are there any clinical data on the effect of measles immune globulin given prior to exposure, as might be done in the midst of an epidemic? I am particularly interested in knowing whether a complete prevention, rather than the desired modification, would result therefrom.

Manasseh Kamen, M.D., Brooklyn.

ANSWER—The immunity against measles produced by immune globulin is a passive immunity similar to that produced by convalescent serum and cannot be counted on to endure longer than two to four weeks. If given prior to exposure, but within the period for which it is effective, it should produce complete protection for that particular exposure. If given more than four days after exposure, but within eight or nine days of exposure, it should result in a modified attack which usually will produce permanent immunity. If one is uncertain as to the exact time of exposure the degree of protection cannot be accurately predicted.

TETANUS AND DIPHTHERIA TOXOIDS

To the Editor:—The following problems have come up at our institution: 1. How long do antitoxin titers against diphtheria and tetanus toxins remain at therapeutic level in the blood following immunization? 2. If an individual receives a dirty wound several years following immunization against tetanus, how soon after a booster shot will the titer be high enough to protect him? The question also applies to diphtheria. 3. Two persons have been immunized against diphtheria and tetanus, and years later one receives a dirty wound and the other is exposed to an active diphtheria case. How should each person be treated?

Harry W. Orris, M.D., New York.

Answer.—1. For a minimum period of two years. Actually, many persons will retain an established active immunity for a much longer time

2 In the circumstances cited, the titer should rise to a high level within seven days and should protect against the disease named

3 The action indicated in regard to the two diseases, diphtheria and tetanus, would not be the same. If a number of years had elapsed since the person with the dirty wound had been immunized against tetanus it would probably be safer to resort to passive immunization rather than rely on a booster dose of tetanus toxoid for protection. In respect to the patient who was exposed to diphtheria, one might wish to know whether infection took place at the time exposure occurred. Consequently, before adopting any prophylactic measures a culture should be taken from the nose and throat to determine whether diphtheria organisms are present, and at the same time a Schick test should be performed for susceptibility If the patient is not susceptible, injections of diphtheria toxoid or diphtheria antitoxin would not be required. If the patient is susceptible but the nose and throat cultures are negative, then a booster dose of diphtheria toxoid would be proper. If the nose and throat culture is positive and the Schick test is also positive, administration of diphtheria antitoxin would be the approved procedure.

AIR IN PERITONEAL CAVITY

To the Editor:—As a general rule, how long after abdominal operation can gas or air be demonstrated by roentgen ray in the peritoneal cavity?

F. K. Hurt, M.D., Jacksonville, Fla.

ANSWER.—The presence of air in the peritoneal cavity is not uncommon following abdominal surgery, particularly when large masses of tissue, such as ovarian cysts or a large fibroid uterus, are removed. The duration of pneumoperitoneum is influenced by several factors, such as the amount of air, the position of the patient in bed and the normalcy of the peritoneum. Factors which influence the amount of air remaining in the peritoneal cavity after abdominal surgery are the length and location of the incision, the position of the patient on the operating table, particularly when the patient is shifted from the Trendelenburg to Fowler's position, the type of anesthesia, straining during the operation and drainage of the peritoneal cavity with tubes. Lewis (*Canad. M.A.J.* 28:18, 1933) reports that pneumoperitoneum is much more common when spinal anesthesia is used, due to the relaxation of the abdominal wall and the tendency to pull up the abdominal wall to the last stitch. He demonstrated air in the peritoneal cavity of 40 per cent of 25 patients when spinal anesthesia was used as compared to 13 per cent of 15 patients when gas, oxygen and ether were employed. He stated further that the major part of the air will disappear in ten days to two weeks, but in a few patients it may persist from four to six weeks. Pain and Rigler (*Surgery* 3:351, 1938) report that if 1,200 to 1,600 cc. of air is injected, pneumoperitoneum may be demonstrated roentgenologically for as long as two weeks. Bannen (*British J. Radiol.* 18:390, 1945) indicates that a small amount of air may be absorbed within twenty-four hours, but larger amounts may persist for fourteen days.

A survey of available literature indicates that ordinarily as little as 20 to 30 cc. of air can be demonstrated roentgenologically by proper positioning of the patient, that small amounts of air are absorbed within twenty-four to forty-eight hours, but that larger amounts may be observed for fourteen or more days subsequent to abdominal surgery, particularly if the patient is placed in Fowler's position; then the air remains under the diaphragm, which is a relatively poor surface for absorption.

UNDULANT FEVER

To the Editor:—Please send me information concerning treatment and diagnosis of undulant fever including use of para-aminobenzoic acid in treatment.

William A. Guenon, M.D., Greencastle, Pa.

ANSWER.—The most reliable criteria for the diagnosis of undulant fever are history of patient, clinical symptoms and signs, a positive agglutination test and a positive blood culture. If the clinical symptoms and signs are suggestive of undulant fever but the agglutination test and blood culture are negative, one may make a skin test with "brucellergen" (a suspension of nucleoprotein from Brucella cells). Caution should be used in interpreting a positive skin test as certain evidence of infection. Those who have had the disease in the past also show a positive cutaneous reaction. Recently two methods of treatment have been developed. One involves the use of sulfadiazine and streptomycin (C. W. Eisele and N. B. McCullough, THE JOURNAL, Dec. 20, 1947, p. 1053) and the other, the administration of sulfadiazine orally and an intravenous transfusion of human blood plasma or whole blood. Instructions for use of the latter method may be obtained by writing to the Brucella Laboratory, Michigan State College, East Lansing.

"ATHLETE'S FOOT"

To the Editor:—The football coach of a Baltimore school has asked me about methods of controlling "athlete's foot." He has some literature on a machine by Peda Spray, Inc., located at 55 West Forty-second Street, New York. This is a clever apparatus but expensive unless effective. Is it worth while installing? I believe there is some evidence that the Navy used it.

Karl W. Ebeling, M.D., Baltimore.

ANSWER.—The Peda Spray machine is attractive and adaptable to any shower room. Mechanically it is simple and effective, in that the solution used reaches the parts of the feet desired. It is stated that one filling of the machine supplies treatment for 11,500 persons. The composition of the solution originally used by the Peda Spray Company was said to be 1.33 per cent salicylic acid, 7.6 per cent camphorated oil, along with a small quantity of eucalyptus oil and menthol, in a base of purified naphthol. According to data supplied by the Peda Spray Company, this formula is capable of destroying in five minutes the parasitic organisms that cause ringworm of the feet. In a report by Capt. H. S. Harding, (MC), U.S.N., to the Bureau of Medicine and Surgery, United States Navy, he was enthusiastic about this solution and this method of prophylaxis. In a recent communication from the president of the Peda Spray Company, it was stated that undecylenic acid is now being added to the Peda Spray solution in the "recommended percentages." Just how effective the present solution is against fungi in aqueous suspension is not stated. Observations by competent dermatologists and mycologists suggest that the greatest value of any method of prophylaxis is the stimulation to the individual to keep his feet clean and dry.

CLAUSTROPHOBIA

To the Editor:—A girl aged 18 has menopausal symptoms—hot flushes, irregular menstruation and also claustrophobia. The history is otherwise noncontributory. The basal metabolic rate is normal. Is estrogenic therapy indicated? Is there indication for some other kind of treatment?

M.D., Massachusetts.

ANSWER.—*In spite of the hot flushes, this is not* a case of premature menopause. The exact type of menstrual disturbance is not mentioned; hence, advice on therapy cannot be given. If the menses are simply far apart or scanty treatment is not necessary at the present time. Estrogenic therapy is not indicated for the hot flushes and irregular menstruation. The claustrophobia is an indication that there is some psychic disturbance, and this may also be responsible for the flushes and menstrual irregularity. For the psychic disturbance some form of psychotherapy is necessary. In addition, a thorough physical examination must be made, including, of course, a bimanual rectoabdominal examination if the girl is a virgin or a vaginal examination if she is not. If any abnormality is found it must be corrected, but almost certainly none will be present. After psychotherapy the flushes will probably disappear.

CHEILITIS

To the Editor:—A man aged 66 has been suffering from glossitis and cheilitis for six months. Nearly all the vitamins, riboflavin 20 to 30 mg. a day, nicotinic acid 200 to 300 mg. a day, vitamin B 20 mg. and vitamins A and C in the same proportion, have been prescribed. He gets good results, but as soon as I cut the dosage to half or to one third, relapse occurs within a week. Examination of blood and urine reveals normal conditions. Reaction to the Wassermann test is negative. He has had false teeth for fifteen years. Does this man need such a large daily dosage of vitamins as long as he lives? Which of the vitamins are indicated for glossitis and which for cheilitis?

H. K. Beshlian, M.D., Paterson, N. J.

ANSWER.—The recitation of treatment the patient received is somewhat obscure, because it is not clear what 20 mg. of vitamin B is. The individual components and their quantities should be stated. The indiscriminate combination of vitamins given is reminiscent of shotgun therapy of former years with other agents. Glossitis and cheilitis that are due to dietary deficiency factors are most apt to respond to administration of members of the vitamin B complex. Of these, nicotinic acid and riboflavin are most frequently effective, the former for the glossitis and the latter for the perlèche. Where individual components are lacking and their supply is effective, it is advantageous to add other members, too. Single factor deficiencies are unlikely to occur. The entire diet of the patient should be reviewed, its adequacy assessed and corrections or modifications made if indicated. Iron therapy and hydrochloric acid are sometimes helpful.

It should be ascertained whether there are other reasons for the glossitis and cheilitis. Is the patient sensitive to something in the composition of the dentures? Do they fit properly? Are they high enough to keep redundant folds from forming at the corners of the mouth with leakage of saliva? If adequate diet alone is insufficient to control this patient's oral changes, then 10 to 20 mg of riboflavin should be tried for its effects and followed by a trial of 100 to 200 mg. of nicotinic acid alone. On the basis of the results obtained it can be ascertained which alone or in combination would be most useful.

DIARRHEAS OF INFANCY

To the Editor:—*The reply in* The Journal, *page 1186, Dec. 27, 1947, to the* question on diarrheas of infancy asked by a physician of Brooklyn stated that fluids should be given parenterally by vein or subcutaneously. There are many conditions in which fluids should be given directly into the blood stream and in which this mode of administration is preferred to the subcutaneous route, as it is more rapid with fewer complications. If use of the intravenous route is impossible, in many cases my associate *and I have used the bone marrow route (Turkel, H., and Bethell, F. H.:* A New and Simple Instrument for Administration of Fluids Through Bone Marrow, *War Med.* 5:222-225 [April] 1944). Several *hundred papers* have been published on the use of the bone marrow route.

Henry Turkel, M.D., Detroit

SENSITIVITY TO ANESTHETICS

To the Editor:-Is there any method of determining the sensitivity of a patient to local anesthetics such as "pontocaine" and cocaine? Has it been determined whether toxic reactions are more common with one or the other of these drugs?

M.D., Maryland.

ANSWER.—Methods to determine the sensitivity of patients to local anesthetics are not always reliable. By applying a patch test or by using a drop of fairly dilute solution (1 per cent) of the agent in the eye, it is possible to get an idea of the way the patient will react, especially to "pontocaine" and cocaine. Inflammatory reaction indicates probable sensitivity. Not infrequently the patient who gives a history of sensitivity to a local anesthetic is more sensitive to the epinephrine used with the local anesthetic than to the anesthetic itself.

Sensitivity of a patient to an anesthetic varies considerably. If sensitivity is only slight the agent is not dangerous for him. If sensitivity exists there is a method which usually reveals this important fact. The patient is seated with his back toward the anesthetist, and the skin of his chest is prepared by painting it with a 70 per cent alcohol solution. A separate syringe and needle are used for each solution. One of the solutions is isotonic solution of sodium chloride; the others are mild solutions (1 per cent or less) of each of the drugs to be tested - in this case "pontocaine" and cocaine.

A control wheal is raised by intracutaneous injection of 1 cc. of isotonic sodium chloride solution. Then at a distance of at least 2 fingerbreadths on one side of this wheal 1 cc. of 0.1 per cent cocaine is injected and on the other side at the same distance from the wheal, 1 cc. of 0.1 per cent "pontocaine" is injected. The wheals which appear are observed for ten minutes. If enlargement and redness occur, the patient is considered sensitive to that drug injected. If the sensitivity is well defined generalized symptoms develop, such as apprehension, shortness of breath, pronounced nervousness, sometimes tremor and pallor, an increase in pulse rate or lowering of blood pressure. In extreme cases the patient will faint. The degree of reaction to the drug determines the degree of sensitivity and also the danger involved in the use of the drug in the person being tested. Various studies concerning poisoning from local anesthetics and treatment used have been reported by D. C. Bull and C. B. Esselstyn (Pantocaine in Spinal Anesthesia, *Ann. Surg.* 103:29-37 [Jan] 1936); A. L. Tatum, A. J. Atkinson and K. H. Collins (Acute Cocaine Poisoning, Its Prophylaxis and Treatment in Laboratory Animals, *J. Pharmacol. & Exper. Therap.* 26:325-335 [Dec] 1925); V. E. Henderson (Toxicity of Anaesthetics, *Bull. Acad. Med., Toronto* 17:113-115 [April] 1944); J. S. Lundy (Clinical Anesthesia, Philadelphia, W. B. Saunders Company, 1942, p. 28), and in Queries and Minor Notes (Sensitivity to Anesthetics, *J.A.M.A.* 126:402 [Oct. 7] 1944).

STREPTOMYCIN

To the Editor:—Has streptomycin by inhalation been tried for pulmonary tuberculosis?, If so, has it been beneficial? Is there available a preparation of streptomycin in oil similar to the standard preparation of penicillin in oil and wax?

Robert S. Srigley, M.D., Hollis, Okla.

ANSWER.—Streptomycin in aerosol sprays has been used in the treatment of laryngeal and bronchial tuberculosis but it has not been used alone in pulmonary tuberculosis unassociated with laryngeal tuberculosis. Parenteral treatment associated with aerosol treatment is more effective in the treatment of laryngeal and pulmonary tuberculosis than aerosol treatment alone.

At present, there are no approved preparations of streptomycin in oil available for parenteral use that are similar to the standard preparation of penicillin in oil and wax.

BARBITURATES

To the Editor:—Does "seconal" 1½ grains (0.1 Gm.) taken every twenty-four hours for a long period of time have an effect on health? Will it shorten life? My patient is nervous and he states that "seconal" calms him. He now has taken it for three years and feels fine.

J. L. Waldner, M.D., Loveland, Colo.

ANSWER.—There is much to be learned regarding the effect on bodily function and life expectancy of the chronic use of the barbiturates. It appears well established that prolonged use of any of the barbituric acid derivatives will lead to tolerance and habituation. Hambourger has stated that one tenth of all drug habituation is due to barbiturates and that in one third of those so habituated a definite craving for the drug is experienced when it is withheld. The chronic use of the barbituates may lead to objective damage of the central nervous system as shown by nystagmus, positive Romberg sign and motility disturbances of a cerebellar nature. Euphoria is common, and in some instances mania may be the end result. In some cases of chronic barbiturate intoxication, convulsions may occur and urticarial rashes are not uncommon. As important as the physical changes which may be produced by the prolonged use of the barbiturates is the postponement of adequate treatment of the causes underlying the use of these drugs. Often they are used to combat unrecognized anxiety states and other neuroses. The proper treatment of such patients lies in adequate exploration of the underlying psychosomatic disease and the institution of appropriate remedial measures rather than the masking of such symptoms by the administration of sedatives.

DIABETIC ACIDOSIS

To the Editor:--Assume that one has a young patient with an intact cardiovascular renal system, who is diabetic and who goes into acidosis because of failure to take the required insulin. He receives insulin and fluids in amounts necessary to restore free urinary output. The aim of treatment is to stop the excessive production of ketone bodies. Therefore, urinary acetone and diacetic acid are checked hourly. Determinations of carbon dioxide combining power are also done hourly. (1) At what carbon dioxide combining power level do the acetone bodies in the urine usually disappear? I have noticed that they disappear while carbon dioxide combining power is still in the low 30's (volumes per cent). If an alkali (sixth-molar sodium lactate or 5 per cent sodium bicarbonate solution) is used, one can raise the carbon dioxide combining power more quickly and abolish the clinical hyperpnea. However, without adequate insulin and carbohydrate, the liver goes on producing acetone bodies in excess, even though the carbon dioxide combining power approaches normal. (2) How does this alkali solution affect the urinary acetone and diacetic acid tests? If the latter tests are made negative, then isn't the use of alkali solution dangerous because it masks the two tests (carbon dioxide combining power and urinary acetone bodies) that reflect the underlying pathologic physiology?

S. Richard Horio, M.D., Honolulu, Hawaii.

ANSWER.—(1) In the type of patient and situation described, it is common clinical experience that tests for acetone bodies in the urine usually become negative when the carbon dioxide combining power of the blood plasma rises to the general level of 25 to 34 volumes per cent. However, there is considerable individual variation due to a number of modifying factors, including the state of renal function and of urinary output, whether or not alkalis have been used in treatment and whether or not sufficient insulin has been given to permit resumption of utilization of carbohydrate. (2) Although the giving of sodium lactate or sodium bicarbonate furnishes base with which excess ketone acids may in part be neutralized, this is not of real value unless insulin is administered early in amounts adequate to allow utilization of carbohydrate, thereby stopping at the source the formation of ketone acids in excess. Unless enough insulin is given, the administration of alkali will not result in negative tests for acetone and diacetic acid in urine (and, in fact, ketosis may occur in alkalosis due to excessive administration of alkalis). Many clinicians successful in the treatment of diabetic coma do not use alkalis at all, and certainly serious errors in the evaluation of a patient's condition are possible when a plasma carbon dioxide value has been made artificially high by the giving of alkali.

MALIGNANT TUMORS OF THE NOSE AND NASAL ACCESSORY SINUSES

LeROY A. SCHALL, M.D.
Boston

MATERIAL

During the past sixteen years, from 1930 to 1945, inclusive, a total of 219 patients with malignant disease of either the nose or the nasal accessory sinuses, or a combination of both, were seen at the Massachusetts Eye and Ear Infirmary. These cases were studied, the diagnosis made by biopsy, and treatment given in the Infirmary, in the X-Ray Department of the Massachusetts General Hospital, or in both, and the cases were followed by the otolaryngological staff in the Tumor Clinic of the Massachusetts General Hospital.

A recent survey[1] reveals that among these 219 cases there were 139 males and 80 females. The average age was 56 years, the youngest patient being 16 and the oldest 83 years of age. Among the 219 cases there were 10 untraced and 62 (30 per cent) with a five year survival or longer.

The relation of the treatment to the survival rate may be summarized:

Primarily surgical treatment		128	Five Year Survival
Surgical treatment alone	21		48 or 37%
Plus roentgen treatment	35		
Plus radium therapy	34		
Plus roentgen and radium therapy	38		
Primarily radiation		72	Five Year Survival
Roentgen therapy alone	59		14 or 19%
Plus surgical treatment	6		
Plus radium	4		
Plus surgery and radium therapy	3		
Primarily radium therapy		10	Five Year Survival
Radium alone	2		0
Plus surgical treatment	1		
Plus roentgen therapy	7		
No treatment		4	

The successful treatment of cancer of the nose and nasal accessory sinuses, as with cancer elsewhere, depends largely upon early diagnosis, upon prompt and thorough treatment; so that the treatment is neither too little nor too late.

If the educational campaign for the eradication of cancer is to succeed, it is necessary that medical students and physicians as well as the general public be made cancer conscious.

SYMPTOMS

The symptoms which may lead one to suspect cancer of this area are few in number and can easily be listed: (1) hemorrhage, (2) nasal obstruction, (3) referred pain to the teeth, (4) painless swelling, (5) paresthesia or anesthesia of the cheek and (6) exophthalmos.

When a new growth is limited to the nasal cavity, nasal obstruction and hemorrhage are the most frequent symptoms. A small growth of the anaplastic type with thin-walled blood vessels may show early ulceration with subsequent hemorrhage as its first symptom. With the increase in size of the growth, nasal obstruction occurs. This obstruction is usually unilateral; hence it is an axiom that any unilateral obstruction by a growth should be considered malignant until the microscope proves it otherwise. When the tumor is of the slowly growing variety, with well developed connective tissue and thick-walled blood vessels, hemorrhage may not occur and the only early symptom is that of nasal obstruction. The growth may have the appearance of a simple nasal polyp; yet on its removal, the hemorrhage may be excessive, and this should be suggestive of cancer. It hardly seems necessary to say that every specimen should be examined microscopically.

ILLUSTRATIVE REPORTS OF CASES

Case 1.—Mrs. I. H. was seen Dec. 11, 1934, by her family physician on account of repeated slight hemorrhages from the left nostril. Examination showed an irregularity along the inferior border of the left inferior turbinate. The biopsy report was epidermoid carcinoma, grade II. The treatment was a left lateral rhinotomy with removal of the entire inferior turbinate followed by 1,032 milligram-hours of radium and 1,600 r of external radiation. The patient has remained free of symptoms.

Case 2.—C. M., aged 38, on Aug. 4, 1937, was brought to the Massachusetts Eye and Ear Infirmary by ambulance on account of severe hemorrhage from the left nostril. She was exsanguinated and required repeated transfusions with postnasal and nasal packing to control the bleeding.

Examination showed an extensive new growth involving the left nostril, the left ethmoid and the maxillary sinus. Roentgenograms showed destruction of the front face of the maxillary antrum, loss of ethmoid cell outline and loss of the nasoantral wall, with superimposed infection. The biopsy report was highly malignant carcinoma. The treatment consisted of as thorough removal of the growth as was possible through a modified Moure approach followed by 3,000 milligram-hours of radium and 2,400 r of external radiation. The patient remains free of disease.

When cancer is superimposed on polypoid ethmoiditis it may be suspected if on the removal of a polyp it bleeds more than usual. I cannot emphasize too strongly the necessity of doing a microscopic examination on any tissue removed from any portion of the body. This is especially true in patients who require repeated polypectomies.

Case 3.—Mrs. E. N., seen Sept. 26, 1942, had had polyps removed every year for about ten years. One month previously, because the bleeding was a little more profuse than usual, her rhinologist suspected malignant disease and had the polyp exam-

Read before the Section on Laryngology, Otology and Rhinology at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1947.

From the Department of Oto-Laryngology of The Massachusetts Eye and Ear Infirmary.

[1] This survey was made possible by a grant from The American Cancer Society, Massachusetts Division.

ined microscopically. The pathologic report was epidermoid carcinoma, grade II.

Examination showed a new growth involving the right ethmoidal labyrinth. She was treated by lateral rhinotomy with 1,000 milligram-hours of radiation followed by 7,100 r of external radiation. She remains alive and well.

Tumors arising in the ethmoidal area may invade the orbit or tumors arising in the orbit may extend to the nasal sinuses. Unilateral exophthalmos without evidence of infection should point toward malignant disease.

Case 4.—Miss S. B., aged 20, was seen in July 1940, giving a history that eight weeks previously the right eye began to water. Treatment of the eye did not give relief and the glands on the right side of the neck became swollen and tender. One week previously she had double vision; she denied having had a head cold or sore throat and said that she did not have a fever at any time. Examination showed an exophthalmos of 4 mm. of the right eye, the eyeball being deviated downward and outward. The nasal septum was straight, in the midline, and the upper part of the vestibule of the right nostril was blocked by a smooth tumor mass apparently springing from the anterior tip of the right middle turbinate. The tonsils had been removed. The postnasal space was normal. The right upper cervical nodes were enlarged, being about 3 cm. in diameter. Roentgen examination showed destruction of the inner wall of the orbit, with a question of pansinusitis.

A biopsy specimen from the right middle turbinate and also a specimen from the cervical gland showed lymphoma. Her treatment consisted of 4,200 r of external radiation, with prompt regression of the tumor mass and the exophthalmos. A recent check-up (October 1946) showed her free of symptoms and disease.

The symptoms of new growth of the maxillary sinus depend somewhat on the location of the growth. Growths originating in the hard palate or the superior alveolus are characterized by early swelling. In the early phase, there is but little pain. With the invasion and destruction of the bone, the teeth may loosen and fall out, but it is a comparatively painless process. Extensive ulceration may develop with fistulization into the maxillary antrum and still be painless. A patient under my care stated that the first symptom which he noticed from a lesion starting in the hard palate was the fact that on drinking, liquids came through his nose.

Lesions originating from the posterior, superior antral wall are characterized by paresthesia or anesthesia of the cheek of that side. They are ofttimes accompanied by pain referable to the teeth. It is not unusual for these patients to seek relief by repeated dental examinations and by the loss of one tooth after another in a vain effort to alleviate the discomfort. As infection is superimposed on the original lesion, there may be early pain referred to the cheek, and puncture and lavage of the antrum has been carried out in many cases. With the increase in size of the new growth, there is extension into the nasal cavity with a mass which may block the entire nostril. Then, too, there is extension into and destruction of the bones of the maxilla, with erosion of the anterior face of the maxillary antrum or destruction of the rim of the orbit. Many patients do not seek medical advice until the growth has reached such a size that there is a mass over the cheek, or until the extension into the orbit has produced exophthalmos.

Case 5.—Mrs. R. E. R., aged 73, seen in the last five year period, illustrates well the symptom of anesthesia of the cheek. Her chief complaint was anesthesia of the right cheek. She described it as a queer sensation and it just did not feel right. She had no difficulty in breathing.

A roentgenogram showed extensive destruction of the right zygoma and the infratemporal fossa with tumor in the roof of the right maxillary sinus. A biopsy specimen taken through a Caldwell-Luc approach revealed epidermoid carcinoma, grade II. In spite of extensive external irradiation, she died a painful death in June 1942.

Pain in the upper teeth without dental disease is suggestive of cancer of the superior posterior part of the maxillary sinus.

Case 6.—J. F., aged 24, in August 1934, after having a dental check-up, experienced severe pain in his left upper teeth. Repeated dental examinations failed to show any pathologic condition in the teeth. The sixth dentist whom he consulted took roentgenograms of his sinuses, and the sinuses were reported as showing chronic infection. In the dentist's office a Caldwell-Luc operation on the left side was attempted with the patient under local anesthesia. On removing the face of the canine fossa, the dentist saw what he interpreted to be a large antral polyp. On removal of the polyp, there was such profuse bleeding that I was called in consultation. The biopsy report was osteogenic sarcoma.

On August 23, a modified Moure operation on the left side revealed that the growth arose from the back wall and the superior part of the left maxillary antrum. The growth was surgically removed as thoroughly as possible and, although osteogenic sarcomas are not radiosensitive, the patient was treated by the local use of radium to the maximum tolerance, followed by the maximum skin tolerance of external radiation. He remained free from his disease for eighteen months, and then one recurrence followed another in rapid succession. His external carotid artery was tied; when exophthalmos developed his orbit was exenterated, and in the next eighteen months he underwent about thirteen major procedures for the removal of fungating growth of the orbit, finally dying in October 1937.

New growths originating in the posterior part of the ethmoidal labyrinth may extend into the sphenoidal sinus, and if the optic nerve is involved, the first symptom is a loss of vision on that side.

Case 7.—Mrs. R. G., aged 45, was seen Feb. 13, 1936. Her first complaint was a sudden loss of vision of the left eye followed by some nasal obstruction. Examination showed a new growth of the left ethmoid and sphenoid sinus. The biopsy report was adenocarcinoma, the treatment consisting of a left lateral rhinotomy and removal of new growth followed by maximum radiation; and external radiation was carried out at the Huntington Memorial Hospital and the Massachusetts Eye and Ear Infirmary. Recurrence developed in 1938 uncontrolled by treatment, with death in 1941.

BIOPSY

I am an advocate of biopsy in every case, for the treatment depends on the type of tumor as shown by the microscopic examination. The biopsy should be done and the findings known so that the plan of treatment can be outlined. I do not agree with those who rely on a frozen section at the time of operation. A low grade lesion may best be treated by operation and radiation, while an anaplastic growth may do better under radiation. A knowledge of the pathologic nature of the tumor is necessary for the plan of treatment.

When in doubt, I am an advocate of an exploratory operation. A lateral rhinotomy, or an external canine fossa operation on the maxillary antrum, in my opinion, in a doubtful case is not only advisable but justifiable.

ROENTGEN EXAMINATION

A unilateral mass obstructing a nasal cavity is suggestive of cancer. The usual roentgen picture of sinus cancer is that of the late stage, when destruction of bone has already taken place. Repeated roentgen examinations in every suspicious case should be the rule, if the diagnosis is to be made early.

TREATMENT

There are but two methods of treatment of cancer of the nose and nasal sinuses that have proved of value; namely, surgical treatment and irradation, or a combination of the two. If the biopsy shows the tumor to be an anaplastic new growth of the radiosensitive type, radiation may be used alone. This can be either in the form of external radiation or by the use of radium. When there is superimposed infection, adequate drainage must be supplied. Occasionally interstitial radiation by the implantation of radium needles directly into the tumor has been of value. When the new growth is not of the anaplastic type, surgical treatment followed by radiation, or the direct implantation of radium in the operative field, supplemented by external radiation, is the treatment of choice.

Operation for Nasal Lesions.—Adequate exposure should be obtained for any operative procedure. New growths limited to the nasal cavity can be adequately exposed through a lateral rhinotomy. This incision starts opposite the inner canthus of the eye and goes down the lateral wall of the nose and around the ala. The periosteum and soft parts are elevated from the bone, and the nasal cavity entered through the lacrimal fossa, followed by the removal of the ascending process of the superior maxilla and the lateral nasal bone. By extending the incision upward, and with bone removal to include the floor of the frontal sinus, access to the frontal sinus can be obtained. This exposure permits access to the ethmoidal region, to the sphenoid, to all of the turbinates; and through this exposure the antrum can be explored. After removal of the new growth, the cavity is lined with petrolatum gauze, packed with narrow-folded strips of gauze, in which radium in either platinum or steel needles can be embedded. An attempt should be made to obtain at least 1 cm. of distance between the septum and the radium. The septum can be further protected by a shield of at least 1 mm. of lead. The packing is brought out the nostril and the incision closed, unless it is desirable to leave it open for further inspection.

Tumors of the Sinuses: The surgical approach to tumors of the sinuses should depend on the point of maximum involvement. If exophthalmos exists and if it is questionable whether the orbit has been invaded the ideal approach is through the orbit by an exenteration of the orbital contents. This approaches the maxillary antrum from above and the ethmoidal labyrinth from the side. By removal of the floor of the orbit, the antrum can be explored; and by removal of the lateral orbital wall, the ethmoidal labyrinth can be exenterated. It permits, too, an easy access to the frontal sinus.

When the lesion has originated in the superior alveolus or from the hard palate with extension into the antrum the ideal approach is from below by resection of the superior alveolus, including half or all of the hard palate. This approach permits access to all the accessory sinuses. It provides the best of drainage, but it handicaps the patient in that he must wear a dental prothesis. Lesions involving the ethmoidal labyrinth and the maxillary sinus without extension into the orbit, or without evident involvement of the hard palate, can be reached by any of the face-splitting operations.

For extensive involvement of sinuses, I have been using a modified Moure incision. This incision starts opposite the inner canthus of the eye, goes down the lateral wall of the nose, around the ala to the midline of the upper lip. It then goes straight down through the columella dividing the upper lip and with an incision through the buccal mucous membrane from the nasal spine to the last molar tooth. The entire cheek is turned back, exposing the superior maxilla. This exposure permits excellent inspection of the operative field and permits the removal of the entire maxilla, if it is found to be necessary.

The incision is made with the cutting electric current, and all bleeders are stopped by electrocoagulation. The bone is removed with rongeur forceps. The tumor is shelled from the antrum by a curet. Its removal is accompanied by a profuse hemorrhage, so that it should be removed rapidly. A large sponge soaked with hot saline solution is inserted into the cavity. The bleeding stops when the tumor is removed. Ligation of the carotid artery has been advocated to control the hemorrhage and to diminish the blood supply of the tumor. I have not found it necessary to ligate the carotid artery in any case.

The ideal removal of any cancerous growth is by its removal through normal tissue. This is absolutely impossible in a region such as the nasal sinuses. Here the removal amounts to a curettage. The operation is ideal for disseminating the growth and producing either distant metastasis or local recurrences. For that reason, the entire operative cavity should be desiccated with the coagulating current. For this reason, too, I have advocated the local insertion of radium to destroy any scattered tumor cells. The orbit is protected with a shield of 1 mm. of lead, the cavity lined with petrolatum gauze, gauze packing is inserted, and the radium placed within the gauze packing so that there is at least 1 cm. of gauze to act as protection. This gauze is brought out and partly through the buccal incision. The musculature of the lip is sutured with buried surgical gut sutures, care being taken that the vermillion border of the lip is approximated exactly. The skin edges are then closed with dermal sutures. Depending on the sensitivity of the tumor, the radium is left in place for a total dosage of 2,000 to 4,000 milligram-hours. At the end of the desired time, with the patient under intravenous anesthesia, the packing is removed through the buccal incision. In the after-treatment, care must be taken that the buccal incision does not close. This can be kept open by an obturator made of dental compound.

Exophthalmos due to radiation reaction occasionally occurs. It is exceedingly painful, and plastic procedure on the lids to preserve the cornea have been of no avail. This reaction may take place early, or it may be delayed as long as six months to one year after radiation. It is a trying situation, as one must think of orbital extension or recurrence within the orbit. Orbital exenteration may be necessary, not only to relieve the pain, but to make certain that extension of the disease has not taken place. Studies of 8 such cases show the pathologic change to be that of edema and fibrosis.

The after-care consists of keeping the cavity clean. The patient can use a nasal irrigation at home with frequent applications of potassium permanganate spray, 1 : 10,000. The discharge ceases in about two to three months. By keeping the buccal incision open, inspection of the operative cavity can be thoroughly made.

This operative procedure of primary closure of the incision in the face leaves the patient with a minimum of deformity and permits the social and business life of the patient to continue without embarrassment.

Irradiation.—When the first supervoltage x-ray apparatus was developed at The Huntington Memorial Hospital in conjunction with the Massachusetts Institute of Technology, it was freely predicted that most operative procedures for cancer would be discarded. I shared in the enthusiasm, but my experience throughout the years has convinced me that the old surgical principles of removal, if only to provide drainage for superimposed infection, and then irradiation, offers the best hope for improving treatment of cancer involving the nose and accessory sinuses.

Our study[1] shows that patients treated primarily by surgery, supplemented by external radiation, or by radiation by means of radium in the operative cavity, have a better than a 2 to 1 chance of a five year survival than those treated primarily by radiation.

CONCLUSIONS

Physicians as well as the laity should become cancer conscious. Early diagnosis followed by adequate treatment is the only hope of saving more patients with cancer of the nose and nasal accessory sinuses.

ABSTRACT OF DISCUSSION

Dr. H. B. Orton, Newark, N. J.: There is little that I can add except to emphasize the fact that we all should be made cancer conscious as well as the general public. This not only applies to cancer of the nose and accessory sinuses, but to other parts of the body as well. Early diagnosis and symptoms leading to a probable diagnosis should be very carefully looked into. To look and see is far better than to wait and see. In the operations of these growths, the tumors that arise from the lower portion of the nasoantral wall have a much better prognosis than those arising above this level. A wide exposure of the area involved should be made in attempting to remove these malignant growths. I am glad to hear Dr. Schall emphasize the importance of statistics based on a five year follow-up. It might be a good rule to have in the various societies that only those statistics based on a five year follow-up be presented, thereby eliminating much of the confusion in relation to the results of the various methods of treatment of cancer not only of the nose and accessory sinuses, but elsewhere in the body. Dr. Schall's percentage of patients living is commendable. It shows that in his locality earlier diagnosis is being made so that appropriate treatment is instituted. There should be no reason why growths originating in the hard palate or superior alveolus should not be diagnosed early. The patient should realize that something is wrong if he looks into his oral cavity; and if he consults a doctor the doctor should see to it that a biopsy is taken. Roentgenograms of sinuses should be encouraged. All tissue removed from the nose or accessory sinuses should be subjected to thorough histologic study. It is surprising to find every so often malignant changes taking place; when the diagnosis is made early the patient has a far better prognosis if proper treatment is instituted. It is extremely interesting to note that Dr. Schall's results with surgical treatment first, followed by some form of irradiation, is far better than in those cases in which he primarily used irradiation. This brings out a point that I have been stressing for some time, namely, that where malignant growths are accessible to operation it should be the procedure of choice.

Dr. G. E. Martin, Edinburgh, Scotland: Dr. Schall's results are extremely good, and this principle of reporting five year survivals is one which I think should be done by every section. We do not want to see the early cases. We can all get good results in a year's time, but what about five years? It is only the five years that count, because, after all, five years added to a man's life at the cancer age, 55 or so, means much, especially if it is five years without discomfort and without pain, and also five years which he can continue with his fellow men. The pendulum has swung both ways as to whether there should be surgical or roentgen therapy. I remember as an intern, seeing an operation in which the surgeon split the face and proceeded to remove the whole of the upper jaw, the eye, part of the forehead and part of the ear, and then, turning, he said, "Gentlemen, I think some people might say this was an heroic operation." It was. The patient was dead an hour afterward. We in Edinburgh pride ourselves on our follow-up cases. We now adopt the principle in most of these cases, not of surgical but of roentgen therapy, plus radium, and there is one point I want to show in that: it is that we find, especially in cases of carcinoma of the antrum, it is important not to remove the tumor. We remove a small part for biopsy, but beyond that, we do nothing more. We put in radium for a short period, regulated by the roentgen service, and then the patient is examined roentgenologically afterward, and with these results our survival figures have gone up; they are now comparable with those shown by Dr. Schall.

Dr. Fred Z. Havens, Rochester, Minn.: There are two points which I should like to mention. In the first place, some of these tumors obstructing the nasal passage may be readily visible, and the physician seeing one may send a biopsy specimen to the laboratory and get a report of no evidence of malignancy. Do not be lulled into a sense of security by such a report, because frequently the anterior portion of such a tumor may be partially necrotic and the pathologist does not have a chance to determine whether cancer is present if such material is submitted for study. Also, particularly if the lesion is small and if you have a good reason to think that it may be carcinomatous, I would suggest that you ask yourself first, "If this is malignant, am I going to take care of it?" If the answer is, "No," then I would suggest that you do not take a biopsy but send the patient to the man of your choice and let him see the lesion in its original state and before its appearance has been obscured by the inflammatory reaction which necessarily follows biopsy.

PERTUSSIS IMMUNIZATION

Use of Two Doses of an Alum-Precipitated Mixture of Diphtheria Toxoid and Pertussis Vaccine

JOSEPH A. BELL, M.D.
Senior Surgeon
United States Public Health Service
Bethesda, Md.

There have been many studies to determine the prophylactic value of pertussis vaccine in children. Lapin[1] and Felton and Willard[2] have reviewed the literature on the subject and presented rather extensive bibliographies. A more cursory and skeptical review was published in England[3] and Prado and his co-workers[4] of Chile and Lewis[5] have reviewed a number of studies. It is difficult to determine what is the best vaccine product for general routine use, because the numerous studies differ from each other in so many respects. They utilize different methods of preparation of the vaccine, different methods of administra-

---

The state and local health departments and local physicians gave cooperation and assistance; the King's Daughters Visiting Nurse Association furnished facilities and special personnel assistance, and Medical Director James P, Leake conducted the study in part of the years 1943-1945. Mrs. Anne Hodges was continuously engaged in the study since 1938. Mrs. Ruth Sargent was engaged from 1938 until relieved by Mrs. Edna McCaleb in 1942. Mrs. Mary Miller relieved Mrs. McCaleb in 1946.

tion and different study procedures. The procedures differ as to environmental groups studied, as to adequacy of observation, as to method of selection and treatment of controls and differ in criteria for evaluating protection against pertussis. After full consideration of these differences, a two dose, pertussis vaccine product was prepared which appeared most practical and suitable for routine use in the general population. An intensively observed and thoroughly controlled study was undertaken, wherein the occurrence of clinical pertussis, as judged by various criteria for diagnosis, would constitute the method for evaluating protection against pertussis. This study was started in 1941 in Norfolk, Va., and vicinity, in cooperation with the King's Daughters Visiting Nurse Association and with the assistance and approval of the state and local health authorities and physicians. The study is still under way, and, hence, several reports will be forthcoming.

SCOPE OF THE REPORT

This report covers an analysis of data collected in this study to March 1, 1947. It is concerned exclusively with answering a single question, as to whether two doses of the alum-precipitated mixture of diphtheria toxoid and pertussis vaccine, containing only 10,000,000,000 phase 1 killed Hemophilus pertussis organisms per dose, given with a four week interval between doses, conferred substantial protection against clinical pertussis. This report is not concerned with other questions, such as those pertaining to reactions, which were few and negligible, and those pertaining to the amount, nature, promptness and duration of protection. Such questions are deferred for later reports, as they require extended analyses of the epidemiologic characteristics of pertussis before they can be properly evaluated.

Questions concerning diphtheria immunity which resulted from the use of two doses of the alum-precipitated mixed product have been evaluated in a previous report on this study.[6] Many details of the study procedures have been omitted from the present report because they were included in the previous report.[6]

MATERIALS

The mixed product used in this study was prepared by mixing 2 parts of crude diphtheria toxoid with 1 part of a pertussis vaccine suspension. The mixture was then precipitated with alum, washed twice and resuspended in isotonic sodium chloride solution. The unmixed product was prepared at the same time, using the same lot of toxoid. It was prepared in an identical manner except that 1 part of isotonic sodium chloride solution was added to the toxoid prior to precipitation instead of adding the pertussis vaccine. Thus, the mixed and unmixed products were identical in every respect except that each dose of the mixed product contained 10,000,000,000 killed H. pertussis organisms and the unmixed product contained no pertussis vaccine. The two products were packaged in twenty-dose vials, and each vial was labeled "A-P diphtheria toxoid." The vials were identical in appearance except that each had a different code number, consisting of three digits. In 1941 Dr. J. P. Leake selected the code numbers from Tippett's "Random Sampling Numbers"[7] and placed them on the vials, so that the sum of the first two digits was odd when the vial contained the mixed product and the sum was even when the vial contained the unmixed product. The contents of the vials could be determined only by the code numbers, and during the observation period this code was unknown to the author and the visiting nurses.

PROCEDURES

The use of two, the mixed and unmixed, products permitted a study arrangement which approaches an epidemiologist's ideal. All of the children received one or the other product, and no one concerned knew which product was given. The products were given from January 1942 to June 1943 to children aged 2 to 23 months who visited the King's Daughters Health Stations in Norfolk, Va., and vicinity. Attendance was stimulated by using birth certificates and sending letters, urging diphtheria and smallpox immunization, to mothers of all children 2 to 12 months of age during the period of inoculation. The products were administered in a routine manner by various local health department personnel, who, together with the recipients, did not know that pertussis vaccine was involved in the study. The personnel gave to each child the product from a vial designated by certain lay persons who had no other connection with the study and who also did not know that pertussis vaccine was involved. The recipients were told that a study of communicable diseases, including diphtheria, was being made and that the children would receive a Schick test one year after immunization to assure their protection against diphtheria. By use of the code numbers on the vials, all children who were born in an odd month (as January, March, May) were to receive the mixed product and children born in an even month (as February, April, June) were to receive the unmixed product. All children who received one or more doses of the study products were under observation from the date of the injection to March 1, 1947, unless they left the study area or otherwise could not be located. Most of the children were under observation since birth. Two full time public health nurses, specially trained in communicable diseases, made routine monthly home visits and made weekly or more frequent visits during the occurrence of communicable

disease in the household. They made records of the clinical symptoms and signs of such diseases and of all known and suspected attributes which might influence the occurrence of such diseases. The nurses worked under my close supervision, and I made household visits as necessary to check the records and to establish diagnoses. Dr. Leake made these visits and conducted the study from July 1943 to July 1945, when I was on overseas duty. To prevent Dr. Leake from knowing which product a child had received, he was given the age rather than the birth date of the children visited and the vial number indicating the product given was concealed with gummed paper. As a minimum, Dr. Leake or I made at least one household visit whenever a study child or any member of his family household had definite or suspicious symptoms of clinical pertussis. The criteria for diagnosis[8] of a definite case of pertussis were the same as that used in another study.[9] Neither the author nor the nurse observers knew that the month of birth determined what product a child was to receive. Throughout the observation period none of the observers knew which child received which product, which child belonged to which group or whether any one child received the same product as any other child. This assured uniform observation and treatment of all children in both groups. This further assured that the two groups, which were comparable at the time the injection was given, would remain comparable throughout the period of observation. There was no way in which the household informants or the investigators could possibly bias the observations in favor of either group and no possible way for them to destroy the comparability of the test and control groups.

ADEQUACY OF PROCEDURES

With the procedures just summarized, a total of 1,238 children, representing 1,164 families, received one or more doses of the mixed or unmixed products at 2 to 23 months of age. All these children received routine monthly medical surveillance in order that the occurrence of pertussis and other common communicable diseases of childhood might be recorded. These children represented 11.3 per cent of all births reported in the study area from January 1941 through April 1943. The procedure for obtaining these children for study, together with their distribution by sex, color and family size, permitted the conclusion in the previous report[6] that they were representative of all children available in the area for voluntary immunization. Thus, the results of the study should reflect what would be expected through routine general use of the study products.

The adequacy of controls in this study was discussed in the previous report,[6] which covered the experience prior to the Schick test. It showed that 52.2 per cent of the 1,238 children were born in an odd month and further showed that in all attributes checked close to 52.2 per cent of the children were born in an odd month. The attributes checked were the sex, color, geographic section of residence, date of the first dose, age at the first dose, breast feeding at first dose, interval between doses, interval from the second dose to the Schick test, age at the time of the Schick test, mother's Schick reaction, number of other children in the household, loss from observation prior to the Schick test, receipt of smallpox vaccine prior to the time of the Schick test, receipt of whooping cough vaccine outside the study prior to the time of the Schick test and occurrence of measles, chickenpox and mumps prior to the time of the Schick test. A further check of the 1,238 children has been made in this analysis of a longer experience for the occurrence of pertussis. The percentage of children born in an odd month of the total under observation during each year from 1941 to 1947 was 51.7, 52.0, 52.9, 52.1, 52.6 and 53.0, respectively. Of the 270 study children who received prophylactic pertussis vaccine from a private physician outside the study, 53.3 per cent were born in an odd month. Of the 792 children in whom the onset of paroxysmal cough of pertussis was not prior to the first dose, who did not receive pertussis vaccine outside the study and who received two doses of the study product, as intended, 51.4 per cent were born in an odd month. Similarly, in all attributes observed, except those influenced by the different study products given, e.g., the Schick reaction and the occurrence of clinical pertussis, close to 52.2 per cent of the children were born in an odd month. Thus, all observations confirmed that the procedure used to divide the children into two nearly equal and strictly comparable groups and to observe and treat them, so that they would remain strictly comparable throughout the observation period, was effective and adequate. Within the range of chance sampling variation, the children born in an odd month are strictly comparable with children born in an even month in all respects except for the different study products given.

---

[8] The following minimal criteria were adopted for the diagnosis of a definite case of clinical pertussis:

(*a*) The child must have a cough lasting longer than eighteen days, and for at least eight days of this time the cough must be unremittently paroxysmal in type and recur at least three times each calendar day of the eight. The paroxysm is defined as a spasm or fit of coughing with a sudden onset at a not definitely predictable time. The child must be practically, if not absolutely, free from cough during the period between paroxysms; due allowance in judgment, however, was permitted for children having coughs due to other causes on which pertussis infection may be superimposed

(*b*) The paroxysm must consist of a rapidly repeated series of coughs, most of which result in almost complete exhalation of supplemental air, as evidenced by history or observation of suffusion of the face and watering of the eyes, and either whooping following most of the series of coughs or the repeated occurrence of four or more successive coughs without intervening inhalation. The intensity of the paroxysm must be sufficient to arouse the child from a deep sleep on many occasions and to cause him, if physically able, to sit up in bed, or at least to get up on his knees to cough and get his breath.

(*c*) Clinical pertussis must be the most likely clinical diagnosis in the judgment of the examining physician, regardless of information concerning a prior attack of pertussis, a recent exposure to the disease or prior vaccination against the disease.

(*d*) The information concerning the clinical syndrome must be sufficiently reliable and complete to establish beyond reasonable question the true existence of the aforementioned minimal criteria.

• RESULTS

Table 1 was prepared to compare the total occurrence of measles, chickenpox, mumps and pertussis in children born in an odd and even month. It covers the entire life experience of each study child from birth to March 1, 1947, or until exit if lost from observation prior to that date. It covers their total experience with these diseases, regardless of whether they actually received pertussis vaccine in or outside the study, regardless of whether they received vaccine at the beginning or the end of the observation period and, in fact, without regard for any attributes which might influence the occurrence of these diseases. Incidentally, 5.3 per cent of the children born in an odd month did not receive pertussis vaccine of any kind during the observation period, whereas 24.8 per cent of the children born in an even month received at least one prophylactic dose of some bacterial pertussis vaccine. Table 1 shows merely the total number of children born in an odd and even month, the average number of years they had lived to March 1, and the total number of cases of these diseases that occurred during their life to the end of their observation period. It shows that the total percentage attacked and the average annual attack rate for measles, chickenpox and mumps is nearly equal in the two groups. In striking contrast the total percentage attacked and the average annual attack rate for pertussis is decidedly lower among children born in an odd month as compared with those born in an even month Another tabulation was prepared showing the attack rate for these diseases by separate six month periods from 1940 to 1947. This tabulation showed that the attack rate for pertussis was uniformly lower in children born in an odd month in every single six month period from 1942 to 1947, whereas no consistent difference between the groups was evident for the other diseases. It is thus obvious that some selective influence other than chance variation produced the difference in the occurrence of pertussis in the two groups. It would appear that this influence lowered the incidence of pertussis in the odd group rather than increasing the incidence in the even group, as the attack rate in the even group is not higher than that usually reported in children in a similar age group. Since the two groups are comparable in every respect with the single exception of the study product given, one can assume that the lowered incidence of pertussis in the odd group was due to the mixed product and can proceed to examine the experience to determine whether the assumption is consistent with all observations.

TABLE 1.—*Comparison of the Total Occurrence of Measles, Chickenpox, Mumps and Pertussis in Children Born in an Odd Month and in an Even Month*

Experience*	Month of Birth Odd	 Even	 Total
Number of children	646	592	1,238
Average no. years observed	4.062	4.054	4.058
No. person-years observed	2,624	2,400	5,024
Measles (no. of cases)	276	244	520
Average annual attack rate (percentage)	10.5	10.2	10.4
Total attacked (percentage)	42.7	41.2	42.0
Chickenpox (no. of cases)	175	179	354
Average annual attack rate (percentage)	6.7	7.5	7.0
Total attacked (percentage)	27.1	30.2	28.6
Mumps (no. of cases)	83	55	138
Average annual attack rate (percentage)	3.2	2.3	2.7
Total attacked (percentage)	12.9	9.3	11.1
Pertussis (no. of cases)	90	211	301
Average annual attack rate (percentage)	3.4	8.8	6.0
Total attacked (percentage)	13.9	35.6	24.3

*This table covers the entire life experience of each study child from birth to March 1, 1947, or until exit if lost from observation prior to March 1. It covers the total experience of these children without regard for immunizations or other attributes which might influence the occurrence of these diseases.

If this assumption is true, then, after excluding children who received pertussis vaccine outside the study, the observed difference in the number of cases of pertussis which occurred in the odd and even groups should be manifest only after, and not before, the children received the study products. Also, when children who had pertussis before the study products were given are excluded. the difference in the occurrence of pertussis among children of the odd and even groups who received two doses of the study products, as intended, should be greater than in the crude experience recorded in table 1. Furthermore, in such children the difference between the groups should be manifest in the white children as well as in the Negro, in boys and in girls and in every other possible attribute by which the children may be subdivided into groups of adequate size.

Table 2 presents some of the tabulations prepared to check these assumptions. It shows that prior to receipt of the study products there was no appreciable difference in the occurrence of pertussis in the odd and the even groups. It also shows that among the 792 children who received two doses of the study products, as intended, 48 cases occurred among the 407 born in an odd month, whereas 158 cases occurred among the 385 children born in an even month. This represents a proportionate difference greater. than that shown in table 1. These 792 children were subdivided into groups according to various attributes, namely, the age at the time of the first dose, date of the first dose, interval between doses, sex, race, geographic section of residence, nurse observer, occurrence of other diseases and immunizations and occurrence of pertussis in other children living in the household. In each of these attributes there were disproportionately fewer cases of pertussis among children born in an odd month as compared with children born in an even month. To exemplify, table 2 includes the attribute of the age at the time of the first dose. It shows that the disproportionately small number of cases that occurred in the odd group was manifest no matter whether the children received their first dose at 2 to 4 months of age or at 5 to 23 months of age. As a further example, one attribute, which is somewhat akin to secondary household exposure, subdivided the children into groups according to whether they had lived in the family household with definite pertussis in another child less than 10 years of age. In the 407 children of the odd group, 109 had such association and 33 (30.6 per cent) were attacked. In the 385 children of the even group, 115 had such association and 100 (87.0 per cent) were attacked. To supplement these observations, further analyses, which will be discussed in future reports, showed that the average annual attack rate in children who received no pertussis vaccine whatsoever was 11.2 per cent, the rate in children receiving only one dose of the mixed product was 8.2 per cent, the rate in children receiving two doses of the mixed product was 3.3 per cent and the rate in children who received three doses of pertussis vaccine outside the study was 4.1 per cent. It is thus obvious that all observations are consistent with the assumption that the mixed product was responsible for the disproportionately few cases of pertussis observed in children born in an odd month.

TABLE 2.—Occurrence of Pertussis Prior to and After Receipt of First Dose of Study Product

Experience	Month of Birth	Age (Mo.) at First Dose	No. of Children	No. of Person-Years Observed	Pertussis: No. of Cases	Pertussis: Total Attacked (Percentage)	Pertussis: Average Annual Attack Rate (Percentage)
Prior to first dose*	Odd		524	332	19	3.0	5.7
	Even		567	294	13	2.3	4.4
After first dose†	Odd	2-4	204	755	28	13.7	3.7
	Even		193	721	83	43.0	11.5
	Odd	5-23	203	686	20	9.9	2.9
	Even		192	671	75	39.1	11.2
	Odd	2-23	407	1,441	48	11.8	3.3
	Even		385	1,392	158	41.0	11.4

* This includes all study children who had no prophylactic pertussis vaccine prior to receipt of first dose of the study product. It covers the experience from the date of birth to the date of the first dose.

† This includes all study children who received two doses of the study product, as intended, who did not have pertussis prior to the first dose and who did not receive prophylactic pertussis vaccine outside the study. It covers the experience from the date of the first dose to March 1, 1947, or to exit if prior to that date.

This conclusion is based on the clinical criteria for definition of a case of pertussis as previously set forth. The clinical basis was used because the ultimate value of any vaccine depends on its ability to ameliorate or prevent the clinical disease. Even though the criteria used in this study are intended to include only frank cases, it is recognized that the criteria are more or less arbitrary. Accordingly, detailed records were kept for each child, noting the occurrence, duration, frequency, nature and intensity of paroxysmal cough, whooping, vomiting and other symptoms and signs of pertussis. The main purpose for collecting this data was to study the clinical disease as it occurs in the community; however, it serves to permit analysis of the data with various arbitrary diagnostic criteria for definition of a case of pertussis. Table 3 arranges the 206 cases of pertussis that occurred in children after they had received two doses of the study products, as intended, and

*TABLE 3.—Clinical Classification, Distribution of Cases of Pertussis in Children of the Odd and Even Groups, According to Duration of Paroxysmal Coughing and Whooping **

Classification	Duration (Days): Paroxysmal Cough	Duration (Days): Whooping	Odd Birth Date (Mixed Product) 407 Children: No. of Cases	Odd Birth Date (Mixed Product) 407 Children: (Percentage)	Even Birth Date (Unmixed Product) 385 Children: No. of Cases	Even Birth Date (Unmixed Product) 385 Children: (Percentage)	Total 792 Children No. of Cases	Ratio Even to Odd (Percentage)
A	9-27	0-27	22	5.41	18	4.68	40	0.87
B	>27	0-27	17	4.18	71	18.44	88	4.41
C	>27	>27	9	2.21	69	17.92	78	8.11
Total cases			48	11.79	158	41.04	206	3.48

* This table includes all study children who received two doses of the study product, as intended, who did not have pertussis prior to the first dose and who did not receive prophylactic pertussis vaccine outside the study. It covers the experience from the date of the first dose to March 1, 1947, or to exit if prior to that date.

no other prophylactic pertussis vaccine, by mutually exclusive groups according to the number of days' duration of paroxysmal coughing and whooping. It shows that the occurrence of the disease with paroxysmal cough of nine to twenty-seven days' duration was nearly equal in the two groups, but that a decided difference occurred in cases in which there was paroxysmal cough for longer than twenty-seven days. This result is amenable to diverse interpretations. It would appear possible that the clinical definition of pertussis used in this study was too broad and possibly included diseases not due to H. pertussis infection. This cannot be denied, but another interpretation seems more likely. The distribution of cases in the even group by the percentage of the total cases in that group should be nearly equal to that in the strictly comparable odd group. By application of the proportionate distribution of the 158 cases seen in the even group, according to clinical classification A, B and C, respectively, 5, 22 and 21 cases, would be expected in the odd group, whereas 22, 17 and 9 cases, respectively, were observed. This would indicate that part of the effect of the mixed product was to modify the clinical manifestations. With either interpretation, the conclusion is inescapable that, if this study had used more conservative criteria for the definition of a clinical case of pertussis, the difference in the observed occurrence of pertussis between the children receiving mixed and those receiving the unmixed product would have been even more striking than with the criteria used.

Incidentally, it may be added that table 3 exemplifies one of the many difficulties involved in efforts to compare the effectiveness of vaccine products used in different studies. In addition to many differences in the conduct of reported studies, table 3 shows that the criteria for diagnosis can produce large differences in results. With the criteria used in this study the percentage attacked in the unvaccinated group was 3.48 times that for the vaccinated group. By use of more conservative criteria the percentage attacked in the unvaccinated group was 8.11 times that of the vaccinated group. Thus, when criteria for diagnosis and other attributes in different studies are not comparable it is difficult to determine whether the product used in one study is more or less efficacious than a product used in another study.

CONCLUSION

It is concluded that two doses of the alum-precipitated mixture of pertussis vaccine and diphtheria toxoid which contained only 10,000,000,000 killed Hemophilus pertussis organisms per dose and which were given routinely to children representing the general *population, with a four week interval between* doses, conferred substantial protection against clinical pertussis when the first dose was given to children either at 2 to 4 or at 5 to 23 months of age.

ASPIRATION OF BONE MARROW FROM THE ILIAC CREST

Comparison of Iliac Crest and Sternal Bone Marrow Studies

MICHAEL A. RUBINSTEIN,
New York

Bone marrow was obtained in living patients for the first time in 1903 independently by Pianese[1] and Wolff.[2] These authors punctured the femur and the tibia respectively in search of another diagnostic aid in detecting parasitic infestation. At first this method of bone marrow study did not gain much recognition, since these sites of puncture in adults normally contain little active marrow and therefore failed to prove of diagnostic value in hematologic investigation.

It was only twenty years later that interest in bone marrow studies in vivo was reawakened when Seyfarth[3] in 1923 trephined the sternum and ribs in order to obtain hemopoietically active bone marrow. It remained for Arinkin[4] further to simplify the procedure by introducing in 1928 the technic of aspiration of the sternum, rendering examination of bone marrow a readily available and routine hematologic procedure. The sternum became the site of election for obtaining bone marrow because it contains normally active bone marrow even in older age groups and was thought to be most suitable for aspiration technic because of its accessibility and the thinness of its cortex.

The aspiration of sternal bone marrow was promptly generally accepted and its diagnostic importance soon recognized. Ever since its introduction it has been almost the only source of bone marrow studies in clinical medicine, so that under "bone marrow examination" one usually understands now "sternal marrow examination."

However, certain inadequacies of aspiration of sternal marrow soon became apparent. In the first place, some technical disadvantages had been recognized. This procedure involving operation with a large needle in the cardiac area usually renders patients apprehensive, in spite of the minimal pain it causes, and not infrequently it is refused before it is done. Moreover, sternal aspiration is not altogether without real danger, as the heart and great vessels are beneath the sternum and the internal mammary arteries run parallel to its borders.

Although only few fatalities have been recorded in the literature,[5] the actual number of fatal outcomes and serious complications (pneumothorax, etc.) is probably much larger. Several such accidents which occurred to well trained hematologists have come to my knowledge in the past few years. Other unreported fatal outcomes of sternal aspiration were told me by many visitors to an exhibit on iliac bone marrow at the meeting of the American Medical Association at Atlantic City, June 1947. These complications occurred chiefly when the bone was found to be exceedingly hard and much force had to be an-

plied to the needle, so that penetration of the inner sternal plate resulted.

Additional complications following sternal puncture have been noted since its introduction for parenteral administration of fluids.[6] These include, besides localized osteomyelitis,[7] complications attributable directly to the topographic situation of the sternum, such as suppurative anterior mediastinitis and infiltration of the pleural cavities with infused fluid, with occasional fatal outcome.[8]

Apart from these technical disadvantages, the diagnostic information gained from sternal aspiration may at times be quite inadequate. This fact has been recognized especially in those pathologic conditions in which the marrow shows patchy rather than diffuse involvement, as in certain instances of aplastic anemia,[9] in myelofibrosis[10] and in metastatic bone lesions in cancers. Other parts of the skeleton than the sternum may become involved earlier. In such instances aspiration of the bone marrow from different parts of the skeleton and especially from the site of a lesion, if it can be visualized, is indicated.

In a case of carcinoma of the breast with roentgen evidence of metastasis in the iliac bone, I attempted early in 1943 aspiration of bone marrow near the site of the lesion in the iliac crest. The aspiration proved easy to perform, but it happened that no neoplastic cells were recovered but instead normal active bone marrow was seen. Since that time I have performed aspirations of marrow from the iliac crest systematically on almost every patient of hematologic interest admitted to the hospital; in many cases studies of sternal bone marrow were done at the same time.

Differential Count of Normal Iliac Marrow

Cells	Range, Percentage
Myeloblasts	0.5-2
Promyelocytes	1-5
Myelocytes, neutrophilic	11-23
Myelocytes, eosinophilic	1-3
Myelocytes, basophilic	0.5-1
Lymphocytes	2-10
Plasma cells	5-2
Hematogones	0-3
Prperythroblasts	0.5-1
Erythroblasts	2-8
Nonsegmented neutrophilic cells	8-21
Segmented neutrophilic cells	5-15
Eosinophils	1-3
Basophils	0.5-2

The present report is based on comparative studies of bone marrow aspirated simultaneously from the iliac crest and sternum in 216 different cases showing normal and pathologic findings. The total number of iliac aspirations, with or without parallel sternal marrow studies, has exceeded one thousand.

TECHNIC

The site for puncture of the iliac bone is chosen on the crest over an area extending within 5 cm. immediately posterior to the anterior superior spine on either side of the body.

According to the thickness of the tegument, a needle, 16 gage, 1 inch to 2½ inches (2.5 to 6.4 cm.) long, and furnished with a stylet, is used for puncture (usually the same type of needle as used for sternal aspiration). A 20 cc. tightly fitted syringe is used for aspiration (a large size syringe is necessary for better suction).

The chosen area is prepared with iodine and alcohol and infiltrated with 2 per cent procaine hydrochloride solution until the periosteum is reached; the periosteal space is then injected extremely slowly. Usually not more than 2 cc. of the procaine solution is required.

The patient usually lies in the supine position; in cases with pronounced abdominal distention (ascites, enlarged viscera) the patient is turned on his side.

The puncture is performed with the needle held in the sagittal plane of the body. When it is inserted it is held at an angle of 45 degrees to the line of the crest and straightened out approximately perpendicular to it at the moment it hits the bone. The needle is then directed over the top of the crest downward (caudad) and pressure applied by the palm of the hand. The needle is forced into the bone with steady pressure and slight rotation.

A distinct "give" sensation is usually felt when the needle enters the medullary cavity. After the needle is firmly embedded in the medullary cavity, the stylet is withdrawn and the syringe attached to the needle. In order to avoid possible admixture of blood, the plunger is slowly withdrawn until the first drop of marrow fluid is visualized in the capillary end of the syringe. Bone marrow aspiration is accompanied by a slight momentary sensation of pain—"suction pain."

The material recovered may be used in the usual way for enumeration of the total nucleated cell count, for preparation of smears and for section studies.

TECHNICAL ADVANTAGES OF ILIAC CREST VERSUS STERNAL PUNCTURE

1. *Safety.*—No serious injury can be sustained by any underlying organ. It is important to have the needle directed from the top of the crest downward toward the lower extremities, and not from the outer surface of the iliac bone toward the abdominal cavity. Most accidents in cases of sternal aspiration occurred when excessive pressure was applied to a hard bone; however, no fear need be entertained in iliac puncture if the needle, when held in the indicated direction over the top of the iliac crest, is forced more deeply into the bone cavity, since there is no danger of penetration of an inner plate.

2. *Ease.*—Usually the iliac puncture, when correctly performed, is less painful during and after its performance, and the patient is less apprehensive than when subjected to a puncture in the cardiac area.

3. *Repeated Aspirations.*—Iliac crest punctures can easily be performed at frequent intervals at both sides of the body. The procedure is suitable for serial studies of bone marrow. These may be important, especially in pharmacologic or cytologic research of hemopoietic tissue and bone marrow tumors.

It is also suggested that the bone marrow cavities of the ilium could be utilized as a route for administering fluids into the general circulation when no intravenous route is accessible, and perhaps may allow for greater safety than the sternal technic. However, such procedures are still in experimental stage and results will be subsequently published.

Some disadvantage of iliac aspiration is occasional difficulty of puncturing the bone, which at times may prove to be exceedingly hard in this region. But even in these instances there is no danger of applying more force when the described technic is used.

REVIEW OF COMPARATIVE STUDIES OF BONE MARROW ASPIRATED FROM ILIAC CREST AND STERNUM

Bone marrow obtained simultaneously from iliac crest and sternum was studied in 216 different cases showing normal and pathologic findings. In addition, about eight hundred other aspirations of the iliac crest without parallel sternal puncture were also studied.

Normal Values.—The normal cell distribution of the iliac bone marrow was found to show approximately the same range as those determined for sternal aspiration. The iliac crest contains hemopoietically active bone marrow in all age groups of all persons studied with normal findings (age range 16 to 78 years).

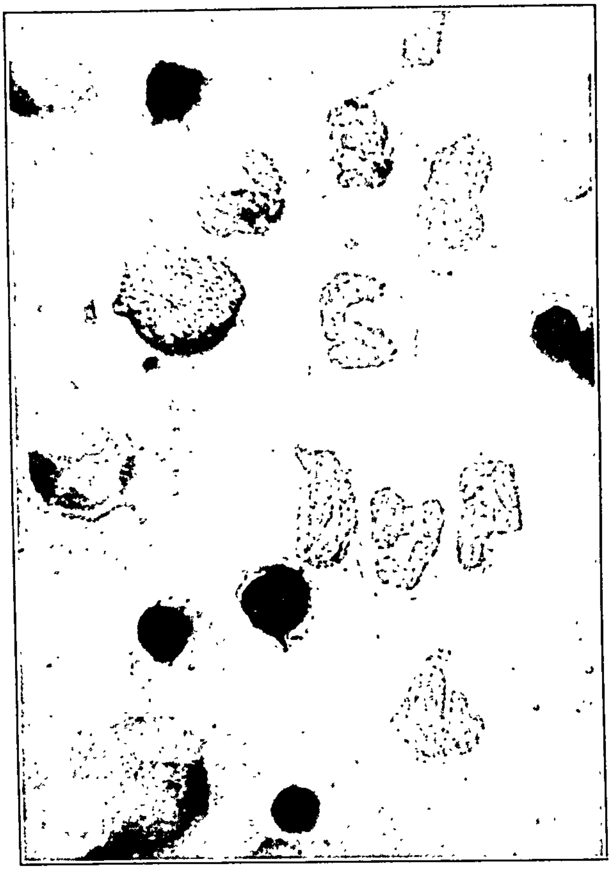

Fig. 1.—Normal iliac marrow.

The total nucleated cell count of the iliac bone marrow, as that of sternal aspiration, tends to decrease with age, falling from the average of 110,000 per cubic millimeter in persons under 20, to 50,000 per cubic millimeter in those over 60.

The differential count of the nucleated cells of the normal iliac marrow is shown in the table.

The number of megakaryocytes ranged between 22 and 88 per cubic millimeter.

The more common types of cells of a normal iliac bone marrow are depicted in figure 1.

Pathologic Pictures.—Comparative studies of iliac and sternal bone marrow were performed in various instances of secondary anemia (posthemorrhagic, iron deficiency, nutritional type), hemolytic anemia (congenital and acquired types, acute and chronic stages), aplastic anemia, pernicious anemia, sprue, osteosclerotic anemia, myelofibrosis, polycythemia, thrombopenic purpura, agranulocytosis (following administration of thiouracil and sulfonamide compounds), Banti's syndrome, Gaucher's disease, Tay-Sach's disease, Hodgkin's disease, follicular lymphoblastoma, leukemias, lymphosarcoma, multiple myeloma, various infectious diseases, renal diseases, cirrhosis of the liver and various neoplastic diseases with or without evidence of bony metastases.

In most of the cases studied the findings from both sources were parallel, and the iliac marrow presented the characteristic picture of the disease as seen in the sternal aspiration.

A few illustrative examples of iliac marrow pictures in various diseases are presented. Aspiration of sternal bone marrow in these cases revealed similar conditions; both aspirations have proved in these instances of equal diagnostic value.

However in certain cases study of iliac marrow has proved of distinct diagnostic advantage as compared to the sternal marrow alone. In some instances sternal aspiration was unsatisfactory, yielding scanty hypocellular marrow, while iliac aspiration showed cellular marrow which proved diagnostic of the disease. However, in other cases, the reverse was true. It is apparent that in some instances the disease (such as metastases, etc.) may invade one part of the bony system earlier than another.

The instances in which iliac aspiration has provided in this study more diagnostic information than the sternal technic may be divided into four groups:

1. In three cases (D. P., J. M. and B. P.) the diagnosis of leukemia, lymphatic or myelogenous, confirmed on postmortem examination, was made first in vivo on the basis of studies of iliac bone marrow. Originally the diagnosis of aplastic anemia (primary in case of D. P.; a secondary effect of administration of a sulfonamide compound in that of J. M.) or of osteosclerotic anemia (B. G.) had been made in those cases on the basis of sternal aspiration, which repeatedly revealed hypocellular bone marrow, and the associated peripheral blood picture (anemia, thrombopenia, leukopenia in the first 2 cases, and a leukemoid blood picture with normoblastosis in the third case). However, bone marrow from the iliac crest showed a picture characteristic respectively of lymphatic or myelogenous leukemia. Subsequently the sternal bone marrow developed the same picture.[11]

2. In 3 instances of multiple myeloma the diagnosis was indicated by studies of iliac bone marrow, showing from 12 to 35 per cent plasma cells, while the studies of sternal marrow were not conclusive. The diagnosis of multiple myeloma in these cases was substantiated by roentgen studies of the bones, studies of blood and urine (hyperglobulinemia and/or Bence-Jones proteinuria) and biopsy of bone lesions. In 2 of these instances associated with thrombopenia and bleeding tendency, sternal aspiration repeatedly showed extremely pronounced admixture of blood with a content of marrow cells too poor to make the diagnosis, while in the third case it showed approximately normal marrow with only 3 per cent plasma cells.

3. In some cases of aplastic anemia and osteosclerotic anemia ("spent" polycythemia) the combined examination of sternal and iliac bone marrow revealed the patchy character of the pathologic process in the bone marrow. In these, sternal aspiration yielded aplastic bone marrow while iliac aspiration showed active islands of hemopoietic tissue; in other cases the reverse was true.

---

[11] These cases of leukemia with hypoplastic sternal bone marrow will be published in detail in collaboration with Dr H. Rifkin

Combined studies of sternal and iliac bone marrow are indicated wherever patchy character of distribution of the disease process in the bone marrow is suspected In 1 case of Gaucher's disease with thrombopenia, sternal aspiration repeatedly yielded bloody nondiagnostic material, while cellular marrow containing the characteristic Gaucher cells was obtained by aspiration from the iliac crest. In all other cases of Gaucher's disease which came to my observation, the diagnosis was made by aspiration of sternal bone marrow.

4. In a number of cases of various types of malignant growths, neoplastic cells were recovered in the marrow aspiration; the neoplastic cells appeared in clumps as well as singly. Such cells were seen more often in the iliac than in the sternal aspiration At times the sternal marrow was negative, while the iliac was positive for neoplastic cells

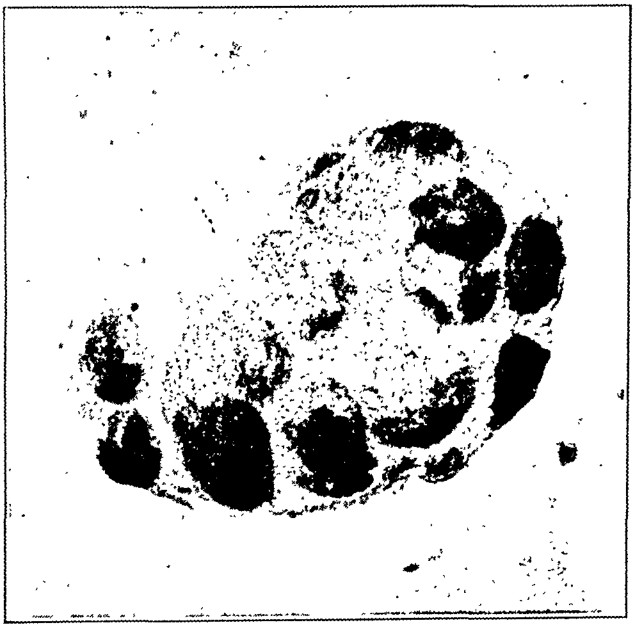

Fig. 2.—Syncytium of tumor cells in marrow in a case of carcinoma of the breast. These cells were found only in the iliac marrow and were absent in the sternal marrow

The importance of a greater possibility of recovering neoplastic cells in iliac bone marrow is threefold

(*a*) Diagnostic: In some cases the first indication of malignancy may be furnished by changes in bone marrow. This was the case of S. S., a man aged 60 years, whose chief complaint was backache; a diagnosis of sacroiliac strain was made. Physical and roentgen examinations did not indicate any abnormality. Because of incidental eosinophilia, studies of bone marrow were done which showed the presence of neoplastic cells. Subsequently roentgen studies showed neoplastic infiltration of lung and metastasis to the lumbar portion of the spine. At autopsy, an anaplastic oat cell carcinoma of the lung was found.

(*b*) Prognostic: Aspiration of bone marrow may present evidence of metastasis in a known case of cancer.

(*c*) Research. iliac bone marrow may serve as a readily accessible material for serial aspiration in following experimental procedures in research on cancer.

ILIAC MARROW AS A SOURCE OF SERIAL ASPIRATIONS

The following 2 cases will briefly be abstracted to show the advantages of iliac puncture technic, enabling serial studies repeated at frequent intervals. Aspiration of sternal bone marrow in 1 case was refused by the patient when it was to be repeated, while in the second case it did not contain the neoplastic cells which could be studied only in the iliac aspiration.

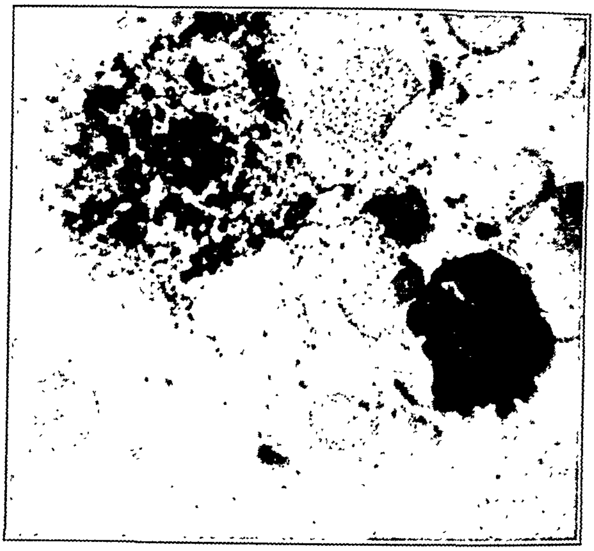

Fig. 3—Iliac marrow in a patient with melanoma showing melanin-laden cells (before thiouracil).

Case 1—S B, a woman aged 58 years, was admitted because of pain in the left lower quadrant of the abdomen, where a mass was felt roentgen studies suggested retroperitoneal tumor Iliac bone marrow puncture yielded black material which showed numerous clumps of melanin-laden cells Sternal aspiration did not reveal abnormality Later, the patient exhibited melanuria

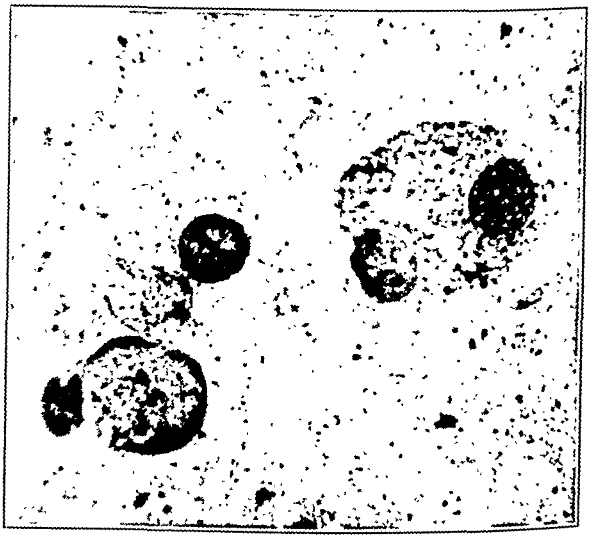

Fig. 4.—Iliac marrow in the same case of melanoma showing diminution of intracellular melanin after thiouracil.

The patient was given thiouracil, after which melanuria stopped.[12] In studies of this case the changes of the melanin content of the cells found in the iliac bone marrow were followed during the course of the experimental therapy Figure 4 shows pronounced decrease of the melanin content of the cells following administration of thiouracil. This diminution occurred gradually, as it was seen in specimens taken every six hours for several days.

---

[12] These experiments with studies of melanin excretions in the urine have been repeated by Dr A White in a personal communication to the author

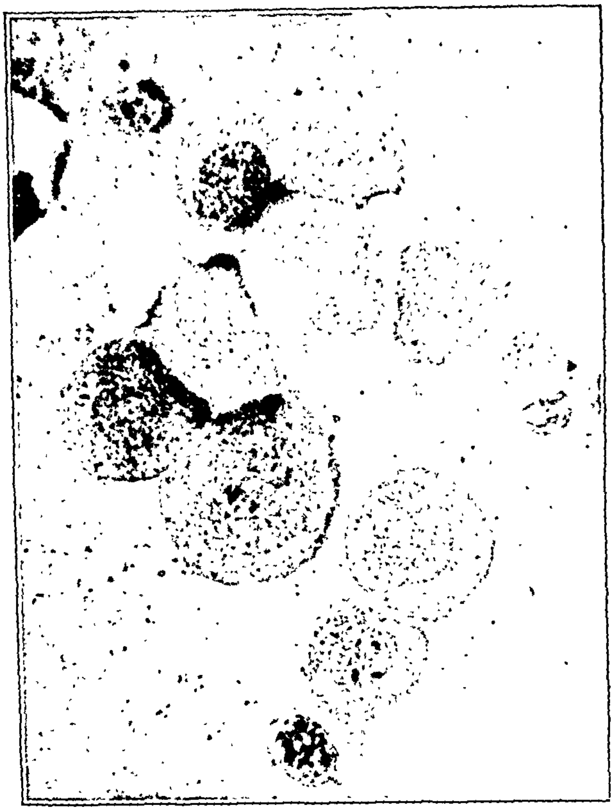

Fig. 5.—Iliac marrow in a case of pernicious anemia before folic acid therapy (megaloblastic marrow)

Case 2.—I. I., a woman aged 61 years, had untreated pernicious anemia with peripheral blood and bone marrow pictures characteristic of a relapse.

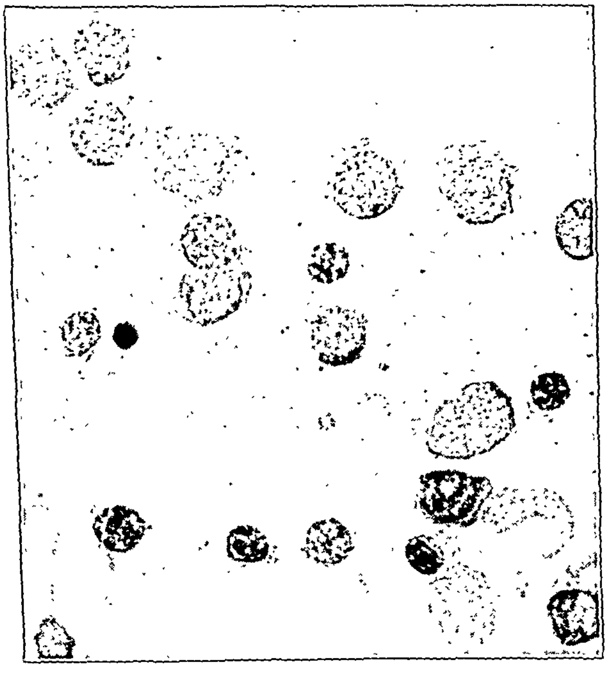

Fig. 6.—Iliac marrow in the same case of pernicious anemia after folic acid therapy (maturation of megaloblasts).

Folic acid in a dose of 40 mg. was injected intravenously and iliac bone marrow was studied at intervals of four to twelve hours for several days. The successive stages of maturation of megaloblasts and the gradual conversion of the characteristic pernicious anemia picture into a normoblastic bone marrow were studied. It was established from these studies that the first sign of folic acid effect on the bone marrow is evident several hours after its administration and precedes by far the response in the peripheral blood (reticulocytes).

The results obtained in these studies will be discussed in detail in separate reports. It is the aim of the present paper only to describe the bone marrow aspiration from the iliac crest and to indicate its advantages and possibilities.

SUMMARY

Bone marrow can be obtained easily, safely and repeatedly from the iliac crest It may provide information at times not obtainable from the sternal aspiration.

The step by step technic of aspiration of bone marrow from the iliac crest is described and its advantages versus the sternal technic are discussed.

The diagnostic advantages of iliac versus sternal bone marrow studies were seen especially in cases of infiltrative diseases of the bone marrow such as metastatic lesions of various neoplastic diseases, and in some instances of multiple myeloma.

NATURE OF THE AQUEOUS HUMOR

SIR STEWART DUKE-ELDER, M. D.
London, England

To be standing here today is one of the big events of my life. It is indeed curious how many of the happiest experiences I have had have occurred in this country or have been associated with Americans in many parts of the world. But to be here as your foreign guest of honor—if, indeed, "foreign' is the correct word—is without doubt the highlight of them all; and to me who knows and likes so many of you and who follows so closely all that you do, it is a pleasurable and moving experience. The more so is it at the moment when you are celebrating your hundredth birthday, when you have grown to the full stature of your maturity not only in nationhood but in the advancement of scientific thought, when, as I said to some of you a year ago, you among all the nations must shoulder the greatest responsibility for the advancement of our subject

These things and the exciting story of your evolution, however, I cannot talk about, for that is the privilege of your American guest of honor—and let me say here that to be bracketed as your guest with Frederick Verhoeff is to me the greatest delight of this meeting. I am under instructions, and, as a good guest should do, I must obey your secretary, who tells me that I am to give a paper on a scientific subject of importance. And so I have looked round for a subject of scientific importance and I have thought of the aqueous humor, partly because the problem of its origin and nature is perhaps the most import-

---

Address of the invited foreign guest read before the Section on Ophthalmology at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, June 11, 1947 ant in ophthalmologic physiology and pathology, and partly because it is an old friend of mine, with which I have spent many happy hours in my laboratory. It is an intriguing and facinating subject, this aqueous humor: Twenty-five years ago I thought that I knew all about it, but, having lived with it for twenty-five years, I find it more complex and elusive than ever, and its secret is further out of reach than it was at the beginning.

It is interesting to glance at the history of the problem, which reflects the history of much of biologic thought. One hundred years ago, when your association was born, it was generally thought that the aqueous humor was a secretion, a view accepted in that age of authority, without any convincing reason, on the dictums of such men as Haller,[1] and Zinn[2] and Vetch.[3] It was a vital process, and at that time such an explanation was sufficient. Toward the turn of the century, in an age when science had turned mechanistic and had accepted a philosophy which was exemplified by the saying of Lord Kelvin in his researches on the atom, that he could understand nothing of which he could not make a model, a simple mechanical view was put forward by Leber[4] and Wessely[5] in Germany and Parsons[6] and Starling[7] in England that the aqueous is a simple filtrate from the blood. A quarter of a century later, at the period when the technics of physicochemistry were being intensively applied to biologic problems, it was found that the chemistry of the aqueous and its energy exchanges are incompatible with a view so simple, and the theory of dialyzation was advanced. And so in the late twenties I sponsored the view that the aqueous is a simple dialysate on which a circulation is imposed by pressure differences, and I must confess, with all the assurance of youth, I protested that this must be so. Since those days knowledge has grown apace, chemistry has attained more subtle and refined methods, to the chemistry of molecules there has been added the physics of radioactive isotopes, and the result is that I know that my early theory, no matter how useful it may have been as a hypothesis, is wrong. Today I do not know what the aqueous humor really is but am vastly intrigued to find out. Neither does any one else know, but fortunately a number of researchers continue to try to solve the problems.

Of recent years especially interesting has been the work done on this subject in America, particularly in Baltimore, Boston and Philadelphia. From those three centers researchers have attacked the dialyzation theory—and rightly, but it is instructive to compare their main lines of attack and their chief conclusions. In a series of long and brilliant researches, Friedenwald[8] has come to the conclusion that the aqueous humor is essentially a secretion of the ciliary body, the necessary energy being derived from differences in oxidation-reduction potential maintained by enzyme systems so that a one way traffic for water and salts exists. On the other hand, Adler[9] and his colleagues have brought forward cogent arguments to show that the iris normally takes prominent part in its formation, while the work of the Boston School, using heavy water as a tracer, leaves little doubt that there must be a free two way transference of water between the blood and the intraocular fluids, for in their view half the water in the aqueous is renewed every three minutes. Again, Adler says that because one of the organic constituents (urea) is in less concentration than in the blood, a secretion must exist in this respect, while the kinetics of inorganic substances, the concentrations of which approximate the Donnan factors, is explicable by dialysis. On the other hand, Cogan, Kinsey and their co-workers[10] affirm the opposite: that because the organic constituents are less their transference is passive and because the inorganic constituents are nearly equal they are secreted. It would seem to me, looking at events from the comparative peace of London, that the easiest way out is to let this second American civil war continue and allow the belligerents to cancel one another out.

I think perhaps that the most unfortunate thing about the work of all of us—including myself—on this aspect of ocular metabolism is that we have been too obsessed with theories, trying to fit our results into the jigsaw puzzle of one or other of them. The more would I press this because I am convinced that none of the theories is correct I am certain that the aqueous is not completely described by the mathematical formulation for a dialysate; I

am equally certain that it is not, in the generally accepted sense of the word, a secretion. To clarify the position let us take each constituent separately—for they all behave differently—and discover for each (1) the dynamics of its penetration into the eye and its exit from it; (2) its concentration in the steady state constituting final equilibrium, and (3) its share in the metabolic activity of the eye. Let us see where such an inquiry leads us in our knowledge today, and I hope that you do not mind if I add some unpublished results from my own laboratory, for I obviously have not the time to go into details about them and am therefore depriving you of adequate grounds for criticism of them.

WATER

The evidence, I think, is strong that the conception I suggested twenty-five years ago is valid—that there is a free and full transference of water reciprocally across most of the blood-aqueous barrier. I should think that Cogan and Kinsey's estimate of a half-renewal of the aqueous every three minutes is probably correct. It seems almost certain that normally a large part of this transference occurs through the iris, whether or not there is a peculiar unidirectional permeability in the ciliary region, as Friedenwald suggests, we do not know. There may be, and if there is, it may be of great importance. It is also certain that superimposed on this diffusion process there is a through and through current with an exit at the canal of Schlemm, and I think that Friedenwald's estimate of 1 to 2 cm. per minute is probably not far from the truth.

SALTS

I have little doubt that the essential mechanism governing the kinetics of the electrolytes is dialysis. I think that we can claim that we have proved this with respect to potassium, which, being relatively free from metabolic implications, is most susceptible to direct proof. The same applies, although less positively, to the other ions—sodium, calcium, chloride, phosphate and so on. It is true that there are some slight deviations from mathematical theory, such as excess of sodium and chlorides. These, however, are of an order susceptible to explanation, on the one hand, such as the leveling out of osmotic differences or changes in the carbon dioxide tension which itself accounts for a difference of 1.5 per cent between the plasma chloride concentrations of arterial and venous blood. On the other hand, the mathematical theory of thermodynamic equilibriums formulated by Donnan[11] may not be entirely and finally correct as applied to the complex body fluids; moreover, the base binding of the plasma proteins which determines the activities of acids and bases between dialysate and mother fluid varies in different members of the same species. The experimental fact remains, however, that the concentrations—or, more accurately, the activities—of these ions more nearly approach the factors for a dialysate, whether they apply to the normal living eye, the perfused living eye or the dead eye, than do other undoubted dialysates, such as ascitic fluid, or in vitro dialysates of plasma through an inert collodion membrane. Finally, if aqueous and plasma are separated by a collodion membrane, little change in the chloride content occurs. Taking the eye as a whole, the the passage of the salts in and out of the eye is equally easy, a circumstance which, incidentally, renders invalid Kinsey and Grant's claim that a continuous flow necessitates a steady state wherein their concentrations should be less. With regard to their kinetics, again taking the eye as a whole, the different ions enter at different speeds—sodium and chloride relatively quickly at about the estimated rate of the drainage of fluid from the anterior chamber; phosphate much slower than this. With regard to the site, the observation of radioactive isotopes shows that the easiest and most rapid entry is into the anterior chamber through the iris; entrance into the posterior part of the eye is much slower and not confined to the ciliary region. Whether or not there is unidirectional permeability there, as Friedenwald suggests, we do not know; if there is it may be important.

SUGAR

Here the evidence is clear. In its steady state the concentration of reducing substance in the eye is of the order that one would expect if its entry were by simple diffusion: It is less than that of the blood by an amount of the order of that used in the metabolism of the lens and retina. As would be expected, it rises in the aphacic eye and falls catastrophically in the incubated eye deprived of its circulation Dynamically, different sugars enter the aqueous in proportion to the size of their molecules. Glucose, 3-methyl-glucose, galactose and xylose enter at approximately the same speed: it is to be noted that 3-methyl-glucose is a synthetic compound not phosphorylated in vivo and therefore not likely to be secreted. The disaccharide, sucrose, on the other hand, penetrates much more slowly; the still larger trisaccharide, raffinose, like the proteins, not at all Most of this traffic occurs through the iris into the anterior chamber; in the case of glucose the rate of penetration into the posterior segment of the eye is only one third of this. Moreover, penetration here is more selective. Although there is no distinction made by the iris, the barrier lining the posterior segment makes a distinction between the hexoses and a pentose (xylose), and the relative rate of penetration of the large-moleculed sucrose posteriorly is but one seventeenth of its rate of penetration

---

[11] Donnan, F.G.: J. Chem. Soc. 99:1554, 1911; 105:1941, 1914

into the anterior chamber. It would seem therefore, so far as sugars are concerned, that there is an inert membrane in the iris allowing the indiscriminate passage of sugars, whether natural or synthetic, into the aqueous as if through pores, the size of the pore being somewhat larger than that of the molecule of sucrose, while in the posterior segment of the eye there is a different type of membrane, more selective in its properties, more discriminating in its functions.

NITROGENOUS SUBSTANCES

The principal nitrogenous substance is urea and Adler, Benham[12] and Kinsey[13] have shown that it is normally in less concentration in the aqueous than in the blood; it varies with the concentration in the blood but with a long time lag, and only when the blood-aqueous barrier is strained by abnormal pressure differences, as by paracentesis, does it approximate the blood level. To these observations I will add others: Not only is the penetration of urea into the chambers of the eye slow, so also is that of creatinine with its readily diffusible molecule, and, more interesting still, the minute amino acids, alanine and glycine. All these enter the eye more slowly than the larger-moleculed sugars. These are facts of which we have to take account. They may be susceptible of several explanations. Thus, as happens elsewhere in the body, penetration of the barrier may be by different routes. Sugars (which are biologically useful) may traverse the cell bodies readily in their passage of the barrier, and nitrogenous substances might find transit difficult unless through the intracellular spaces when these were stretched mechanically. At any rate, granted their slow and difficult penetration, the low concentration of urea is explicable qualitatively on Kinsey and Grant's conception of the steady state reached as a result of a restricted entrance and a freer exit. An explanation of this phenomenon can thus be advanced on simple lines, but it is necessary to conclude that the blood-aqueous barrier is complex and individualistic, probably more complex than most of us have anticipated, treating each constituent in a characteristic way. It is to be noted that this conception of relative impermeability does not imply secretion unless we propose to strain the connotation of this term to describe the properties of the envelope of the red blood corpuscle.

My main thesis, therefore, is that there is no single intraocular fluid which can be discussed as an entity; that each constituent varies in its kinetics and must be considered separately; that there are at least two mechanisms in operation—a relatively simple traffic through the iris mainly into the anterior chamber and a more discriminating and subtle one in the posterior segment of the eye, and that about either, particularly the latter, we do not yet have enough facts to form a foundation whereon a structure of theory can usefully be built.

And in the erection of such a structure we should exercise the greater care, since it is of fundamental importance; for on our ideas of the kinetics of the intraocular fluid must depend much of our ideas on the basal physiology and therefore the pathology of the eye, particularly on the metabolism of the lens and that congeries of different pathologic conditions which, as if to mislead ourselves, we still place under the single label of glaucoma. It is obvious that the control of the intraocular pressure is not governed by the simple laws depending on hydrostatic and osmotic pressures which determine the behavior of a dialysate. There are regulating mechanisms of which we have some inklings only. Some fifteen years ago I demonstrated the presence of axon reflexes in the eye—the only internal organ in the body wherein they have been shown to occur. The unique presence of these significant reflexes here must surely have a meaning. In the first place it would seem probable that acute congestive glaucoma may sometimes be determined by an uncontrolled riot of these reflexes affecting primarily the anterior segment of the eye; the control of these reflexes in the eye, their bilateral association with the other eye, and their possible distant control from some regulating center, perhaps in the hypothalmic region, are indeed most intriguing subjects on which knowledge is yet completely lacking. In the second place, it may be that some forms of chronic glaucoma may be determined by more gradual disturbance—perhaps of a sclerotic or degenerative type—of the more specific mechanism in the posterior segment of the eye and the ciliary body, and sometimes, perhaps of the retina and optic nerve.

This, of course, is largely speculative. In the meantime we require many more facts, even although they may seem disparate and unconnected. Our present knowledge is as yet too fragmentary and incomplete to support a philosophy of synthesis and integration. But we are making progress. Armed with new technics which make our inquiries into these problems twenty years ago almost childishly clumsy and crude, there is no reason why we should not go on apace and reach exciting conclusions within measurable time. And I am certain that, when your children's children celebrate their bicentenary, the story which will then be told of the kinetics of the intraocular fluids and the pressure of the eye will be one of the most fascinating in biology, and I am also certain that one of its landmarks will be the surge of research and the revitalization of ophthalmology which is marking the middle of the present century in America.

and
WILLARD C. STONER, M.D.,
Cleveland.

Many new treatments for peptic ulcer continue to appear in the literature. Some of these treatments are discarded after a brief period. In evaluating the results of any treatment in peptic ulcer, caution must be exercised, because some ulcers heal spontaneously or with little treatment.

Interest has been stimulated by Co Tui and his associates[1] in the treatment of peptic ulcer with protein hydrolysate. They reported favorably on the use of protein hydrolysate in 30 patients with peptic ulcer. Hodges[2] reported favorably on 26 patients and Kimble[3] reported favorably on 11 out of the 15 patients with peptic ulcer treated with protein hydrolysate.

The purpose of this study is to evaluate the effectiveness of the oral administration of protein hydrolysate in the treatment of peptic ulcer.

Co Tui[1] stated that there is a protein deficiency in a large number of patients with peptic ulcer. We were unable to duplicate this observation among our private patients with peptic ulcer. However, in our outpatient clinics we have seen some undernourished patients who show a protein deficiency, but this is seen in patients with other diseases as well as in those with peptic ulcer. Hodges[2] made serum protein determinations in 18 patients with peptic ulcer immediately before and on completion of treatment with protein hydrolysate. In only 1 was the initial value below 6 Gm. per hundred cubic centimeters. Eleven of his patients showed a higher level of serum protein before treatment than after completion of treatment.

One of the most important factors in the treatment of peptic ulcer is the neutralization of the free acid in the stomach. We concentrated our efforts in determining the value of protein hydrolysate as a buffering agent in the stomach. Dragstedt has repeatedly stated that the medical management of peptic ulcer has been successful directly in proportion to the degree in which the acid gastric juice has been neutralized during the entire twenty-four hours.

INFLUENCE OF PROTEIN HYDROLYSATE ON THE FREE AND TOTAL ACIDITY OF GASTRIC JUICE

Fifty subjects were used for this study. All observations were made on patients on the medical services. We did not limit this study to patients with gastrointestinal disease. In each instance the patient presented himself in a fasting state; a Levine tube was introduced through the nose into the stomach, and the fasting contents were withdrawn. Five-tenths of a milligram of histamine dihydrochloride was then injected hypodermically in some of the patients. Samples of gastric juice were then aspirated at fifteen minute intervals for one hour. A test meal, consisting of various doses of protein hydrolysate in 250 cc. of water, was introduced through the tube, and a sample of gastric juice was again aspirated every fifteen minutes for two hours. The test specimens were titrated in the usual manner with tenth-normal sodium hydroxide, using Toepfer's reagent and phenolphthalein as indicators, and the free and total acidity were determined. The color of the protein hydrolysate mixture made the end point somewhat difficult to detect, but this was corrected by diluting the specimen with distilled water before titration.

The effect of 25 Gm. of protein hydrolysate on the free and total acidity is shown in table 1. In figure 1, there are two typical curves made from the data taken from the first 2 cases in table 1. These curves show that when protein hydrolysate is introduced into the patient's stomach there is a decided reduction in the free acidity and a definite

increase in the values for total acidity. The amino acids are all amphoteric, ionizing both as acids and as bases by virtue of their carboxyl and amino groups, thus forming salts with alkalies and with acids. The curves also show a sharp rise in the free acidity after the period of neutralization, and in most of the cases the free acid at the end of the period of neutralization returned to a figure above the initial values, as shown in table 1.

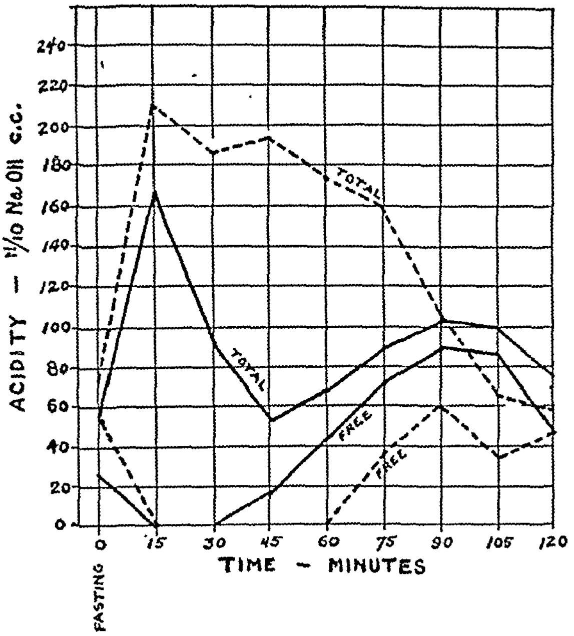

Fig. 1.—The effect of the administration of 25 Gm. of protein hydrolysate in 250 cc. of water on the free and total acidity. Data are of the first 2 subjects listed in table 1—M. G., with peptic ulcer (indicated by the unbroken line), and M. M., a normal subject (indicated by the broken line). The upper curves show the total acidity, and the lower curves show free acidity.

The high values for total acid are due to the presence of amino acid in the stomach. When the amino acid leaves the stomach, as is evidenced by a drop in the values for total acid, the free acid begins to rise rapidly (Figure 1). The total acid dropped more rapidly in the patient with peptic ulcer because the stomach emptied more rapidly, while in the patient without ulcer, the stomach emptied more slowly, causing a more gradual drop in total acid. In each case there is a rise in the free acid to a point higher than the level of the free acid during the fasting state.

In figure 2, the curve shows the effect of protein hydrolysate on the free acidity in a patient who was fed 25 Gm. of protein hydrolysate in 250 cc. of water every hour. The free acidity dropped to 0 from an initial value of 38 degrees, and remained at 0 for 45 minutes. At the end of one hour the free acidity rose to 22 degrees, at which time the patient was given another feeding of 25 Gm. of protein hydrolysate in 250 cc. of water. The free acid again dropped to 0 and this time remained at 0 for only 30 minutes, at the end of which it rose sharply, reaching 57 degrees at the end of the second hour, which was higher than the initial value during the fasting state. At the end of two hours the patient was given a third feeding of 25 Gm. of protein hydrolysate in 250 cc. of water. There was a decline of free acid to 16 degrees, but the free acid was not completely neutralized at this time. From 16 degrees the free acid rose until at the end of the third hour it reached 73 degrees, which was the highest it had ever been.

TABLE 2.—*The Effect of the Administration of 25 Gm. of Protein Hydrolysate in 250 Cc. of Water on the Free Acidity in the Stomach*

Time (Min.)	Free Acid (Degrees)	Time (Min.)	Free Acid (Degrees)	Time (Min.)	Free Acid (Degrees)
Fasting	38	Feeding 2		Feeding 3	
15	0	75	0	135	23
30	0	90	0	150	15
45	0	105	41	165	47
60	22	120	57	180	73

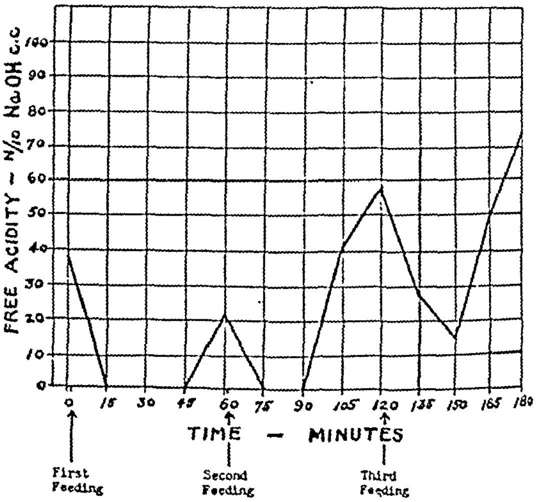

Fig. 2.—The effect of hourly feeding of 25 Gm. of protein hydrolysate in 250 cc. of water on the free acidity in the stomach. Table 2 shows the same results as are depicted in the chart.

Thus, figure 2 demonstrates that protein hydrolysate when given in small doses every hour will eventually cease to neutralize the free acid in the stomach and will cause the free acid to rise much higher than the initial value.

LENGTH OF TIME THE FREE ACID REMAINS BUFFERED IN THE STOMACH AFTER THE ADMINISTRATION OF PROTEIN HYDROLYSATE MIXTURES

The results are shown in table 3. Fifty subjects were used, and they were divided into five groups of 10 persons each.

In the first group of 10 subjects, who were given 50 Gm. of protein hydrolysate in 250 cc. of water, there was no free acid for 75 minutes in all 10, for 90 minutes in 7 subjects, for 105 minutes in 6 subjects and for 120 minutes in 2 subjects.

The second group of 10 subjects were given 50 Gm. of a commercial preparation of protein hydrolysate containing 46 per cent carbohydrate (maltose and sucrose) with vitamins, in 250 cc. of water. There was no free acid for 30 minutes in all 10 subjects, for 45 minutes in 9 subjects, for 60 minutes in 4 subjects and for 75 minutes in 2 subjects.

TABLE 3.—*Number of Subjects Exhibiting No Free Acid at Successive Fifteen Minute Intervals Following Ingestion of Various Protein Hydrolysate Mixtures*

Protein Hydrolysate Mixtures	Number of Subjects Showing Anacidity Time Interval After Protein Hydrolysate Feeding 15 Min.	30 Min.	45 Min.	60 Min.	75 Min.	90 Min.	105 Min.	120 Min.
Protein hydrolysate 50 Gm.	10	10	10	10	10	7	6	2
Protein hydrolysate, carbohydrate 46%, vitamins 50 Gm.	10	10	9	4	2	1	1	0
Protein hydrolysate 25 Gm.	10	10	7	2	0	0	0	0
Protein hydrolysate 25 Gm., cream 50 Cc.	10	10	10	7	5	0	0	0
Protein hydrolysate 25 Gm., theobroma oil 10 Gm.	10	8	8	5	3	2	2	2

The third group of 10 subjects were given 25 Gm. of plain protein hydrolysate in 250 cc. of water. There was no free acid for 30 minutes in all 10 subjects, for 45 minutes in 7 subjects and for 60 minutes in 2 subjects.

The fourth group of 10 subjects were given a mixture of 25 Gm. of protein hydrolysate and 50 cc. of cream in 200 cc. of water. The cream was added to determine whether the fat would prolong the length of time that the free acid would remain buffered in the stomach. There was no free acid for 45 minutes in all 10 subjects, for 60 minutes in 7 subjects, for 75 minutes in 5 subjects and for over 75 minutes in none of the subjects.

The fifth group of 10 subjects were given a mixture containing 25 Gm. of protein hydrolysate and 10 Gm. of theobroma oil (powdered) in 200 cc. of water There was no free acid for 15 minutes in all 10 subjects, for 30 minutes in 8 subjects, for 45 minutes in 8 subjects, for 60 minutes in 5 subjects, for 75 minutes in 3 subjects and for 90 minutes in 2 subjects.

EFFECT OF PROTEIN HYDROLYSATE ON THE GASTRIC EMPTYING TIME

Eleven patients were used for this study. Each patient was given 60 Gm. of barium sulfate in 200 cc. of water, and the normal emptying time was observed by repeated roentgenograms every 30 minutes until the stomach was empty. After the normal gastric emptying time had been determined, the effects of the addition of 25 Gm. of protein hydrolysate to this barium-water mixture were studied in each person.

Table 4 shows that 25 Gm. of protein hydrolysate when added to the barium-water mixture will delay the gastric emptying time two hours or more in 6 out of 8 cases, and one and a half hours in the other 2 cases.

In order to determine whether the buffering of the acid in the stomach had some influence on the delay in the gastric emptying time, 5 subjects were given a mixture of barium and water, to which was added 30 cc. of aluminum hydroxide gel. There was little delay in the gastric emptying time. Two of the 5 subjects were given protein hydrolysate, barium and water mixture on the previous day and the gastric emptying time studied, so that these various mixtures could be tried on the same subjects for comparison. The buffering of the acid in the stomach apparently was not responsible for the delay in the gastric emptying time. Thomas and Crider[4] have demonstrated that there is an inhibition of gastric motility when the end products of protein digestion are placed in the upper part of the small intestine.

RESULTS OF CONTINUOUS INTRAGASTRIC DRIP OF PROTEIN HYDROLYSATE

Twenty-two patients were admitted to the hospital for management of peptic ulcer and received the following treatment after a diagnosis of ulcer was confirmed by roentgenogram: Bed rest and a bland diet consisting of three meals a day with milk and crackers between meals were prescribed. A soft latex tube[5] was inserted through the nose into the cardiac portion of the stomach. The tube remained in place for two weeks, and through it was administered a continuous drip of 10 per cent protein hydrolysate, at the rate of 30 drops per minute. Three thousand cubic centimeters of this solution, containing 300 Gm. of protein hydrolysate, was used in twenty-four hours for the fourteen days.

A serum protein determination was made for each patient before treatment was begun. In no instance was the level of serum protein below 6 Gm. per hundred cubic centimeters.

While the patients received the continuous drip treatment with a 10 per cent solution of protein hydrolysate, random specimens were aspirated from the patient's stomach during the day and during the night, and in most instances free acid was observed in the stomach, in spite of the continuous drip of protein hydrolysate.

[5] Woldman, E. E.: A Collapsible Indwelling Nasogastric Tube, Am. J. Digest. Dis. 4: 428-429 (Sept) 1937.

Ulcer pain continued for twenty-four to seventy-two hours while patients received this form of treatment. In some instances there was a recurrence of pain during the course of treatment.

One month after the treatment had been discontinued, 8 of the 22 patients had a recurrence of ulcer symptoms.

COMMENT

In evaluating the effectiveness of protein hydrolysate in the treatment for ulcer one must ask how this product aids in the healing of an ulcer.

Additional proteins are unnecessary in a patient whose serum proteins are normal and in whom there is a positive nitrogen balance; consequently, more proteins would not aid in healing a peptic ulcer.

From the results obtained it is to be seen that protein hydrolysate decidedly reduces the free acidity and causes a definite increase in the values for total acidity. The prolonged acid neutralization action of protein hydrolysate has been previously noted by Levy and Siler,[6] Co Tui[1] and others. However, little importance was attributed to the rise in acidity above the original level following the period of neutralization or to the fact that repeated small doses of protein hydrolysate will eventually cease to neutralize the acid in the stomach. This was demonstrated in our cases when continuous drip with protein hydrolysate was given and also after hourly feedings of 25 Gm. of protein hydrolysate.

Protein hydrolysate buffers free acid as long as it remains in the stomach; however, when it leaves the stomach there is apparently a stimulation of the production of more free acid to a higher level than the original level during the fasting state. The length of time of the period of neutralization is dependent on the gastric emptying time; in other words, the longer the protein hydrolysate remains in the stomach the longer will be the period of neutralization. We also observed that the larger the dose of protein hydrolysate the more prolonged was the gastric emptying time.

The values for total acidity remained high as long as the amino acids remained in the stomach, and a drop in the total acidity apparently occurred when the amino acids were expelled from the stomach. An interesting observation was the fact that the level of free acidity began to rise when the amino acids left the stomach and entered the small intestine, and the level of total acidity rose parallel with the free acidity. The presence of the amino acids in the upper part of the small intestine apparently causes a hormone to be liberated which stimulates the secretion of hydrochloric acid.

The buffering property, which is necessary in the healing of an ulcer, is present in protein hydrolysate, but the sharp rise in the level of gastric free acidity which follows its administration has its disadvantages. Another disadvantage is the fact that protein hydrolysate ceases to have any buffering properties after repeated small doses. It appears from our observations that the presence of protein hydrolysate in the upper part of the small intestine stimulates acid secretion faster than it can be buffered by further small doses in the stomach.

Clinically there is also evidence that this method of treatment is inadequate. Pain subsides more slowly when protein hydrolysate is used to neutralize the acid than when other antacids are given. Pain frequently recurs during the continuous drip treatment, which we have never observed with aluminum hydroxide therapy.[7] There was also rapid recurrence of ulcer symptoms after treatment has ceased in several cases. Complications of peptic ulcer during treatment with protein hydrolysate have been reported by several investigators. Ruggiero and his associates[8] reported that 2 patients in their study experienced massive gastrointestinal hemorrhage while receiving protein hydrolysate. In 2 of the patients the ulcers became perforated during the first week of the treatment. Hodges[2] reported a serious gastrointestinal hemorrhage on the tenth day of treatment in 1 of his patients receiving protein hydrolysate. During the past twelve years we have not encountered a single complication during the course of treatment with aluminum hydroxide for peptic ulcer.[7]

SUMMARY AND CONCLUSIONS

There was no evidence of protein deficiency in any of the 22 patients with peptic ulcer in this study. Therefore additional proteins are not an important part of treatment for peptic ulcer if the patient is receiving a well balanced diet.

A single dose of protein hydrolysate causes a decrease in the free acid and an increase in the total acid of the stomach. The period of neutralization varies with the amount of protein hydrolysate administered into the stomach.

There is a sharp rise in the free acidity in the stomach after the period of neutralization with protein hydrolysate, and the amount of free acid reaches a higher level than the initial level during the fasting state.

Multiple doses of 25 Gm. of protein hydrolysate every hour will cease to neutralize

free hydrochloric acid in the stomach. The continuous drip of a 10 per cent solution of protein hydrolysate fails to neutralize free hydrochloric acid in the stomach.

Protein hydrolysate delays the emptying time of the stomach two hours when given as a single dose.

Ulcer pain continued for twenty four to seventy-two hours while patients were treated with protein hydrolysate. The ulcer pain disappeared immediately in the patients receiving aluminum hydroxide gel.

Recurrence of the ulcer within a short period after treatment is commoner during treatment with protein hydrolysate.

Complications, such as hemorrhage and perforation, have been reported to have occurred while patients were being treated with protein hydrolysate, but there were no such complications resulting from our use of aluminum hydroxide during the past twelve years.

Protein hydrolysate is of value only as a food, but has little value as a therapeutic agent for peptic ulcer.

GRANULOMA INGUINALE

Treatment With Streptomycin

LYDIA C. MARSHAK, M.D.
and
JACK RODRIQUEZ, M.D.
Chicago

Valuable information regarding the causation, clinical manifestations and treatment of granuloma inguinale has recently been added to the knowledge of this disease.

The causative agent, the Donovan body, is an encapsulated ovoid safety-pin-like organism which can readily be demonstrated in stained smears of tissue scrapings from lesions of granuloma inguinale. Ever since its discovery by Donovan,[1] in 1905, it has been regarded as a protozoan. All attempts to grow the Donovan body on ordinary culture mediums had been inconclusive until Anderson, De Monbreun and Goodpasture,[2] in 1945, were successful in isolating and cultivating it in the egg yolk of the developing chick embryo. After observing it in continuous serial cultures, they came to the conclusion that this organism is a gram-negative bipolar bacillus. These authors suggested naming it 'Donovania granulomatis.'"

Lesions of granuloma inguinale are most frequently seen about the genitalia, but extragenital lesions (mouth, larynx, face, neck and eyelids) have also been described.[3] In our series of 122 patients,[4] observed from November 1943 to May 1947, there were 88 patients, or 72.1 per cent, who showed lesions limited exclusively to the external genitalia. Inguinal folds were involved in 20 patients (in combination with genital lesions in 18 of them). Lesions located chiefly on the perineum, perianal area, pubis and thighs were present in 12 patients and on the cervix in 1. A solitary extragenital lesion on the lower part of the abdomen was encountered in 1 instance.

Gardner and Kelly,[5] in 1928 were first to diagnose granuloma inguinale of the cervix. Several investigators[6] thereafter emphasized the importance of such lesions, which can easily be confused with malignant cervical growth and have been shown to involve the uterus, parametrium and adnexa. Pund and McInnes,[7] on the basis of 3 cases in which the disease was fatal, pointed out the dubious prognosis of cervical granuloma inguinale in pregnant women.

Granuloma inguinale is not limited strictly to the skin and the corium. Greenblatt, Dienst, Pund and Torpin [8] observed the pathognomonic organisms of granuloma inguinale in the regional lymph nodes even though no associated adenopathy was apparent. Sobel and Pensky[9] reported a case of granuloma inguinale with "bubonuli" (lymphangitic abscesses) on the dorsum of the penis. Two of our patients with granuloma inguinale presented Donovan bodies in material aspirated from a fluctuant inguinal bubo. The frequent involvement of the regional lymphatic system, following initial lesions, points to the associated lymphatic pathogenesis of the disease.

That granuloma inguinale can be regarded as

[9] Sobel, N., and Pensky, N.: Bubonulus in Granuloma Inguinale, Arch. Dermat. & Syph. 48:498 (Nov.) 1943.

a systemic disease has been shown by Lyford and his co-workers,[10] in 1944, and Sheldon,[11] in 1945, who described cases of polyarthritis and osteomyelitis due to granuloma inguinale. Lyford's patient died of disseminated granuloma with multiple bone and joint involvement. Metastatic lesions in bones and skin, with severe constitutional symptoms, were observed by Paggi and Hull.[12] Postmortem examination revealing lesions of granuloma inguinale in the abdominal viscera and bones of the thorax was reported by Humphreys.[13]

Treatment with antimonial preparations has been generally accepted as having a specific healing effect on lesions of granuloma inguinale. In our series of 122 patients, 64[14] were adequately treated with antimonial drugs and were observed by us at regular intervals. Complete healing was evidenced in 57 patients,[15] or 89.1 per cent, of these 64 patients. The remaining 7 patients[16] (10.9 per cent) failed to respond to any number of courses of various antimonial preparations, administered regularly over a period of from one to three years. Antimony resistance in granuloma inguinale has been mentioned by others as well.[17] Robinson and his co-workers,[18] in a study of 46 patients treated with one or another of the antimony drugs, observed that only 60.8 per cent showed satisfactory response.

Toxic reactions (nausea, vomiting and generalized aching) were observed in many of our patients treated with larger doses of antimonial preparations, particularly with antimony potassium tartrate. These complications, in some cases, accounted for irregular treatment, with subsequent delay in healing of the lesions. Greenblatt and his co-workers[8] reported 2 fatalities due to antimonial preparations.

Surgical excision of small lesions has been reported as successful in cases of chemoresistant disease.[18] We, however, have observed two recurrences of lesions in the scar tissue following radical vulvectomy. None of the other methods of local treatment (roentgen therapy and fulguration) has been reported to show satisfactory results. Twenty-five per cent podophyllum suspension[19] applied locally in 7 of our cases, in addition to antimony treatment, had to be discontinued in 3 cases, because of severe burning and swelling.[20] In the other 4 cases, resolution of lesions appeared to be accelerated.

The discovery of the bacillary nature of the Donovan bodies[2] led to the thought that one or another of the antibiotics would prove to be of value in the treatment of granuloma inguinale. Several investigators demonstrated the ineffectiveness of penicillin in controlling this disease.[21] No change in the appearance of granulomatous lesions was apparent in 12 of our patients with concomitant syphilis who were given up to 4,800,000 units of penicillin over seven and one-half days.

Greenblatt, Kupperman and Dienst,[22] in a recent publication, reported 23 cases in which granuloma inguinale responded favorably to streptomycin therapy. Barton, Craig, Schwemlein and Bauer[23] described the action of streptomycin on lesions of granuloma inguinale in their report of 3 patients treated at the Chicago Intensive Treatment Center in February and March 1946. The following study includes a brief résumé of these 3 cases, with the latest follow-up observations, and a report on 8 additional patients treated with streptomycin. In each case the following laboratory studies were made: complete blood cell count, urinalysis, dark field examination, cultures for gonococci, serologic test for syphilis and roentgenogram of the chest. Examination of the spinal fluid was made in patients with concomitant syphilis. Only relevant abnormal laboratory observations are reported.[24]

REPORT OF CASES

CASE 1 (*a* and *b*).—M.N., a 26 year old Negro woman, with characteristic lesions of granuloma inguinale and "woody" edema of the vulva of fifteen months' duration, was treated with streptomycin from Feb. 20, 1946, through April 1 (0.02 Gm.

[24] Biopsy specimens were examined by Dr. Marcus R. Caro, clinical associate professor of dermatology University of Illinois.

every three hours for a total of 6.16 Gm. in forty-one days). At the end of the treatment, all lesions appeared epithelized and the edema was reduced. Donovan bodies, which were seen in smears of tissue scrapings prior to administration of streptomycin, could no longer be demonstrated after the fifteenth day of treatment. Seven months later, a minute open lesion reappeared at the anterior aspect of the fourchette. In January 1947, large granulating ulcers on the vulva, similar to the original ones, were present, and there was also a recurrence of the "woody" edema. Smears from tissue scrapings showed Donovan bodies, and the biopsy confirmed the diagnosis of granuloma inguinale. Treatment with streptomycin was resumed on January 29 through February 27 (0.05 Gm. every three hours for a total of 11.45 Gm. in thirty days). Continuous healing was observed from day to day, with complete epithelization of lesions at the end of treatment. Donovan bodies could no longer be seen after the ninth day of treatment. On August 15, or five and a half months later, the only residue was a slight swelling of the vulva.

CASE 2.—This case represents possible failure of response to streptomycin therapy.

E.H., a Negro presented a lesion of granuloma inguinale on the coronal sulcus of two months' duration. He was given 0.03 Gm. every three hours over a period of eighteen days for a total of 4.1 Gm. At the end of treatment, the lesion was completely epithelized and Donovan bodies could no longer be demonstrated. There was recurrence of the same lesion three weeks after treatment was discontinued, and the patient was successfully retreated with antimony potassium tartrate.

CASE 3.—A.M., a 21 year old Negro woman, presented typical granuloma inguinale lesions on the posterior aspect of the fourchette, of eight months' duration. She was given 0.03 Gm. of streptomycin every three hours, for a total dose of 7.05 Gm., from March 3 through April 1, 1946 (twenty-nine days) Ten days after treatment with streptomycin was started, Donovan bodies were no longer demonstrable in stained smears of the lesion. On June 17 all lesions were completely epithelized, and they had remained so when last observed on July 17, 1947 (fifteen months after treatment).

CASE 4.—F.W., a 19 year old Negro woman, was admitted in May 1946, showing characteristic granulomatous ulcerations, with a rolled border, on the fourchette (fig. 1A). The lesions were of two months' duration. Donovan bodies were seen in smears from tissue scrapings, and the observations in biopsy were consistent with granuloma inguinale. A total of 3.4 Gm. of streptomycin was administered from June 18 through July 10 (0.02 Gm. every three hours for twenty-three days). After the first week of treatment, the lesion appeared smaller and less moist and Donovan bodies were no longer demonstrable. At the end of treatment the lesion was completely healed (fig. 1B) and had remained so at the patient's last visit, ten months later.

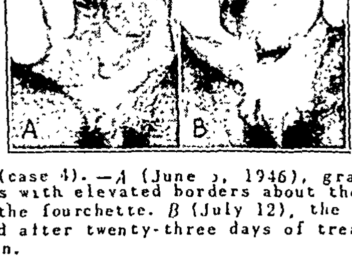

Fig. 1 (case 4).—*A* (June 5, 1946), granulomatous ulcerations with elevated borders about the posterior aspect of the fourchette. *B* (July 12), the lesions are epithelized after twenty-three days of treatment with streptomycin.

CASE 5.—C.F., a 38 year old Negro, was admitted on May 18, 1946, presenting irregular ulcerations and "woody" edema of the penis, of two months' duration. The quantitative serologic test for syphilis showed 40 Kahn units. Results in dark field examination for Treponema pallidum were negative. Donovan bodies were seen in smears from tissue scrapings. Cerebrospinal fluid showed 20 Kahn units, 70 lymphocytes, 31 mg. per hundred cubic centimeters of total protein and a negative colloidal gold curve. A diagnosis of asymptomatic neurosyphilis and granuloma inguinale was made, and the patient was given 2,400,000 units of penicillin, 600 mg. of bismuth compound and 300 mg. of dichlorophenarsine hydrochloride between May 21 and May 29. There was no change in the appearance of the lesions at the end of this treatment. From June 4 through June 29, streptomycin was administered (0.02 Gm. every three hours for a total of 4 Gm. in twenty-five days). Donovan bodies could no longer be seen after the twelfth day of treatment. On July 10, all lesions were epithelized. In March 1947, eight months later, a recurrence of penile lesions similar to the original ones was observed and Donovan bodies were again shown to be present in smears from tissue scrapings. Because of poor follow-up possibilities this patient was retreated with antimony potassium tartrate.

CASE 6.—L. H., a 36 year old Negro woman, was admitted on March 3, 1946, with cicatricial and granulomatous lesions of ten years' duration, involving the entire perineal and both inguinal regions, where numerous draining sinuses were present. Operation had been recently performed for an associated rectal stricture. Donovan bodies were demonstrated in a biopsy specimen of the lesions. There was no response to treatment with various antimonial preparations administered off and on since 1937, nor to various courses of antimonial therapy during four months' hospitalization prior to streptomycin therapy. Profuse drainage from the open sinuses in the groin persisted, and no change in the aspect of the lesions was noticeable. A course of penicillin (3,800,000 units in fourteen days) also proved ineffective. Streptomycin (0 03 Gm. every three hours for a total of 3.62 Gm.) was then administered from July 29 through August 19 (there was a lapse of six days), when treatment had to be terminated due to the exhaustion of our supply. At that time, all lesions were epithelized and the sinuses appeared to be closed or practically dry Because of inadequate dosage of streptomycin, it was deemed advisable to continue outpatient treatment with antimonial drugs. When the patient was last examined, on July 19, 1947, all lesions had remained healed.

CASE 7. D. L., a 23 year old Negro, was admitted on Oct. 10, 1946, presenting a granulomatous ulcer with elevated pearly edges on the frenulum, of four months' duration. Donovan bodies were demonstrated in spreads from scrapings of the lesions. Streptomycin was administered from October 14 through November 12 (0.03 Gm. every three hours, for a total of 7.35 Gm. in thirty days). Donovan bodies were no longer seen after two days' treatment, and two weeks later the ulcer was completely healed, with some residual edema of the prepuce. When last seen, eight months after treatment, no trace of the original lesion was evident.

CASE 8. J. R., a 27 year old Negro woman, was admitted on Aug. 26, 1946, presenting "beefy" lesions on the vulva, perineum and inguinal folds, of three years' duration. "Woody" edema of the labia majora (about three times normal size) was present. Donovan bodies were revealed in tissue scrapings. On September 5, streptomycin therapy was started (0.05 Gm. every three hours). On September 21, after administration of 6.175 Gm. in sixteen days, treatment was discontinued because of exhaustion of our supply of the drug. There was a distinct epithelization at the periphery of the lesions, and Donovan bodies were no longer demonstrable after the first week of treatment. Continuous healing was noted from day to day after streptomycin injections had been discontinued. When last seen, ten months after treatment, smooth depigmented scar tissue had replaced all previous lesions and the vulva was normal in size.

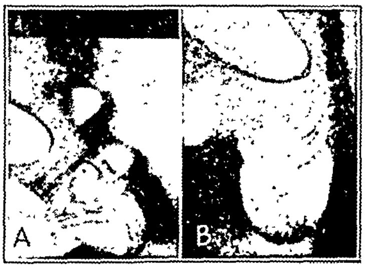

Fig. 2 (case 10).—Granuloma inguinale. *A* (May 27, 1947), elevated papuloerosive lesions on the prepuce and the frenulum. *B* (June 15), the lesions are flattened out and epithelized after twenty days of treatment with streptomycin.

Summary of 11 Cases of Granuloma Inguinale in Which Treatment Was with Streptomycin

Case No.	Patient*	Age (Yr.)	Sex	Duration of Lesions Prior to Treatment	Previous Treatment	Total Dose Streptomycin, (Gm.)	Treatment Period (Days)	Status at End of Treatment	Latest Post-Treatment Observation	Donovan Before Treatment	Bodies Disappearance Days after Beginning of Treatment
1 *(a)*	M.N.	25	F	15 mo.	None	5.45	41	Edema reduced, all lesions epithelized	Relapse in 7 mo.	Present	15
1 *(b)*	M.N.	25	F	7 mo.	Streptomycin	11.4	39	Edema reduced; lesions completely epithelized	Remained healed 5½ mo.	Present	7
2	E.H.	25	M	2 mo.	None	4.11	19	Lesion completely epithelized	Relapse in 3 weeks	Present	14
3	A.M.	21		9 mo.	None	7.05	29	Almost completely epithelized	Remained healed 15 mo. after treatment.	Present	19
4	F.W.	19	F	2 mo.	None	3.4	23	Lesions completely epithelized	Remained healed 10 mo. after treatment	Present	5
5	C.F.	32	M	2 mo.	None	4.0	25	All lesions epithelized	Relapse in 3 mo.	Present	12
6	L.H.	35	F	10 ys.	Antimonial treatment off and on since 1937; 4 mo. routine treatment in hospital	3.9	15	All lesions epithelized	Remained healed 11 mo. after treatment	Present	Not Checked
7	D.L.	23	M	4 mo.	None	7.3	20	Lesions completely epithelized	Remained healed 3 mo. after treatment	Present	2
8	J.R.	27	F	3 yr.	None	5.1	15	Two thirds of all lesions epithelized.	Remained healed 10 mo. after treatment	Present	9
9	W.G.	33	F	9 Mo.	Verified antimonial treatment for 15 mo.	10.25	29	Lesions completely epithelized	Remained healed 5 mo. after treatment	Present	9
10	A.J.	56	M	3 weeks	Verified antimonial treatment for 2½ yr.	12.15	20	Lesions completely epithelized	Remained healed 2 mo. after treatment	Present	9
11	H.M.	50	M	29 yr.	Verified antimonial treatment for 10 yr.	5.75	13	Lesions reduced one-third original size	Further involution of lesions after 2 mo.	Present	9

*All 11 patients were Negro.

CASE 9.—W. G., a 33 year old Negro woman, was first seen in October 1944, presenting large moist papilliform vegetations on the vulva, of eight months' duration. Donovan bodies were demonstrated in spreads from the lesions. From October 1944 to January 1947, she was treated regularly with various antimonial drugs, one to three times a week, practically without interruption. A certain degree of scar formation was noticed at times, but the lesions never healed, and there were periods of definite progression. Donovan bodies were still demonstrated in smears from tissue scrapings at the end of the described treatment. The lesions were considered to be resistant to antimonial preparations, and streptomycin was administered from January 28 through February 25 (0.05 Gm. every three hours for a total of 10.25 Gm. in twenty-nine days). Donovan bodies were no longer seen in tissue scrapings, and the lesions showed decided involution after the ninth day of treatment. At the end of treatment all papillomatous vegetations were replaced by depigmented scar tissue. When the patient was last examined, five months later, all lesions had remained healed.

CASE 10.—A. J., a 53 year old Negro, was treated for a dark field positive chancre in August 1945 with 2,400,000 units of penicillin given in seven and a half days. The lesion failed to heal, and three weeks after completion of treatment it presented the clinical appearance of early granuloma inguinale. Donovan bodies were present in tissue spreads from the lesion. From September until May 1947, the patient was regularly and adequately treated with various antimonial preparations. At the end of the aforementioned treatment, the lesions had the same moist granulating appearance (fig. 2*A*) and spreads for Donovan bodies were still positive. Streptomycin therapy was started on May 28, and 0.08 Gm. was administered every three hours until June 16 (12.16 Gm. in twenty days). After the ninth day of treatment, the lesions appeared smaller and Donovan bodies could no longer be demonstrated. At the end of the treatment, the lesions were completely epithelized (fig. 2*B*), and they had remained so at the patient's last visit, two months later.

CASE 11.—H. M., a 51 year old Negro, was admitted on May 25, 1947, with exuberant papillomatous vegetations occupying the scrotum, perianal region and both inguinal folds. Donovan bodies were revealed in smears from tissue scrapings. The patient dated the onset of these lesions from World War I, about twenty-eight years previously. Verified records revealed treatment with various antimonial preparations in different clinics since 1938. Three months prior to admission, he received injections of antimony potassium tartrate (every second day for a total of 133 cc.) in our outpatient department. No change in the lesions was noticeable, and Donovan bodies were still present in tissue spreads at the end of the aforementioned course of treatment. Streptomycin was given from May 27, 1947, to June 13 (0.05 Gm. every three hours for a total of 6.75 Gm. in eighteen days). Donovan bodies could no longer be seen after the ninth day of treatment. At the end of treatment the lesions showed an involution to one third of their original size. Slow but progressive healing, with scar formation, was noticeable on the patient's last visit, five weeks later

COMMENT

The therapeutic response of granuloma inguinale to streptomycin in our series of cases further substantiates the work of Anderson, DeMonbreun and Goodpasture,[2] who showed that the Donovan body is a gram-negative bipolar bacillus.

In our series of 122 patients, the exclusive localization of over 70 per cent of granuloma inguinale lesions on the genitalia showed some variation from the usual textbook description of the disease as being largely limited to the inguinal regions.

Evidence presented by other investigators and by us attests to the associated lymphatic pathogenesis of granuloma inguinale, which may possibly account for the rare disseminated type.

Streptomycin appears to be a valuable drug in the treatment of granuloma inguinale, particularly in those patients whose disease fails to respond to various antimonial drugs over a period of many years.

As demonstrated in the table, 3 patients experienced a relapse. The total dosage of these 3 varied from 4 to 6.4 Gm., given over a period of eighteen to forty-one days. The total dosage of those with favorable response ranged from 3.4 to 12.16 Gm., administered over a period of fifteen to thirty days. It is apparent, therefore, that the evaluation of this study must be regarded as a preliminary one. The total dose and time-dose relationship are yet to be determined. The scarcity of streptomycin at the time of this study was responsible for the low and variable dosage

None of the complications, such as cutaneous eruptions, vertigo or deafness, as described by others.[25] was encountered in our group of 11 patients. This was possibly due to the low dosage employed.

SUMMARY

Eleven patients with lesions of granuloma inguinale were treated with streptomycin. All patients showed an immediate favorable response, with disappearance of Donovan bodies and healing of lesions. A progressive resolution of the lesions was observed long after discontinuation of streptomycin therapy. Four patients, with lesions of from two to twenty-eight years' duration, whose disease had been resistant to antimonial therapy, showed prompt response to streptomycin. Three patients presented relapse after a period of three weeks to eight months. No sign of developing resistance to streptomycin was observed in 1 patient retreated after a relapse. Eight patients had been observed, as of the time of writing, for two to fifteen months and showed no evidence of relapse.

QUESTION OF CARDIAC HYPERTROPHY IN RESIDENTS OF HIGH ALTITUDES

GONZALO ESGUERRA GOMEZ, M.D.*
Bogotá, Colombia

The Republic of Colombia, located at the northwestern corner of South America, is a tropical country. For this reason there are no seasonal changes in the whole of its territory, as there are in the Temperate Zone. The temperature is uniform all through the year in all the cities, but it varies in accordance with the altitude above sea level at which they are located. It is therefore erroneous to believe, as some residents of the Temperate Zone do, that every tropical city enjoys a hot climate. This is true only of those that are located at sea level. As the altitude increases the temperature drops, and it is for this reason that the city of Bogotá, the capital of Colombia, built on a plateau at 8,016 feet (2,440 meters) above sea level, has a normal temperature of 14.55 C. (58 F.); that is to say, a relatively cold climate.

The considerable altitude of Bogota in relation to sea level has long caused it to be the subject of discussion as to the adaptation of the human organism to the plateau.

In the year 1945, Dr. A.M. Barriga Villalba, professor of physics of the school of Medicine of Bogotá, presented to the Medical Academy a documented study on the greater task to which the heart was subjected on the plateau.[1]

Among the conclusions reached in that study

Address of the invited foreign guest read before the Section on Radiology at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J. June 11, 1947.

Due to lack of space chart 4 has been omitted from THE JOURNAL but will appear in the author's reprints.

*Professor of Radiology at the School of Medicine of Bogotá, Colombia.

[1] Barriga Villalba, A. M.: The Work of the Heart at High Altitudes, Rev. med., Bogotá 47:319 (Oct.) 1945

was the supposition of the existence of a relative cardiac hypertrophy in the residents of the city of Bogota, as was apparently demonstrated in the roentgenologic studies conducted in the same city by Dr. Benigno Jiménez[2] and those conducted in Oroya, Peru, at an altitude of 12,000 feet (3,660 meters), by A. J. Kerwin.[3]

Dr. Francisco Gnecco Mozo, without refuting the facts that a greater task is imposed on the heart and that there is a compensating hypertrophy at high altitudes, supported the theory that at 8,016 feet, at which height Bogotá is located, there was no increase in the work imposed on the heart, and certainly no cardiac hypertrophy either.[4]

For these reasons I thought it necessary to conduct a careful study on the subject, in order to confirm or to invalidate the hypotheses relative to a possible cardiac hypertrophy in the residents of the city of Bogotá. My first observations were presented to the Academy of Medicine in the year 1945,[5] and in this paper I wish to complete them with further research carried out since then.

Both cardiac hypertrophy accompanied by enlargement and concentric hypertrophy without any increase in the size of the heart can be confirmed in the autopsies on persons who died of causes that do not affect the heart. Unfortunately there are few such cases in Bogota, and therefore I dispensed with that type of investigation.

METHODS OF DETERMINING HYPERTROPHY

For determining whether there existed an increase in the size of the heart, it was necessary to examine a considerable number of normal persons by a simple process which offered the least possibility of error, and by trying to eliminate the subjective appreciation of the results.

I did not consider the clinical approach because, although percussion permits the limitation of the cardiac area, it is a slow process and must be performed by an expert clinician if it is to be of any value.

I should have liked to use the orthodiagram, this being the most precise method, and to take advantage of the prediction tables of the important research conducted by Drs. Hodges and Eyster,[6] but unfortunately it would have required excessive work to gather the necessary observations, and, futhermore, the personal factor would have intervened appreciably.

I then thought that teleroentgenography was the most appropriate process. If not so accurate as the orthodiagram, at least it could be easily realized. And as the percentage of error never reaches even 10 per cent,[7] the results obtained on examining a large group are completely satisfactory.

But I omitted the evaluation of the cardiac area and the longitudinal and oblique diameters of the heart because, for obtaining them, one has to fix the points, to the right and to the left, where the cardiac curve ends and where the vascular curve begins, which lends itself to individual variations of appreciation.

Therefore I restricted my investigation to the study of the transverse cardiac diameter, not taking it separately, but in relation to the weight and height of the persons examined. I dispensed with the cardiothoracic relation because it is well known today to be of little value.

The study of the transverse diameter, or of any other measurement which serves for estimating the size of the heart, is of no value whatever unless its relation to the height and weight of the person examined be established. A definite relationship is known to exist between the weight, the height and the linear measurements of the different cardiac chambers.[8] From the studies of C. P. Clark[9] it is known that the circumferences of the thorax and of the abdomen vary with the index weight/height, and it is supposed that a similar relation might exist between the transverse diameter of the heart and this anthropometric index. And, finally, I have arrived at the conclusion and the conviction that the biologic constant established by Ungerleider and Clark[10] is correct. That constant, evaluating the weight and the height of the persons examined in pounds and inches, is as follows:

$$\frac{\text{Weight x } 100{,}000}{\text{Height x (Diameter)}^2} = 13.83$$

And taking, as I have done, the weight and the height in kilograms and in centimeters, I obtained the following results:

$$\frac{\text{Weight x } 100{,}000}{\text{Height x (Diameter)}^2} = 2.47$$

All of the roentgenograms were taken at a distance of about 6 feet (183 cm.), with a moderate inspiration and with an exposure of one-tenth second The persons examined were weighed without coats, and a corresponding deduction for shoes was made in the height.

RESULTS

My first studies were conducted on 120 medical students who either were born in or had lived in the city of Bogota for more than four years, to which I added the cases presented by Dr. Jimenez[2], with which it was intended to demonstrate the existence of a slight cardiac enlargement. The first thing that attracted my attention was to find that the observations made by Jimenez based on the diameters and the cardiac area for proving the existence of a relative hypertrophy were normal when the transverse diameter of the heart was related to the anthropometric index. And the second fact to occupy my attention was that the group of students added to the cases of Dr. Jimenez fitted in normally to the prediction tables prepared by Ungerleider and Gubner[11] with a definite preponderance of point zero and with a percentage of 84.07 of the persons examined falling between plus 10 and minus 10 per cent (chart 1).

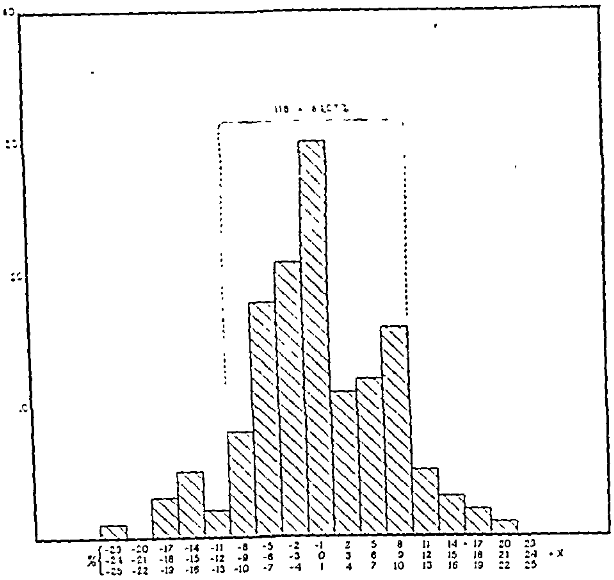

Chart 1.—Histogram of 138 persons examined in Bogota that fitted in normally with the prediction tables of Ungerleider and Gubner, with decided preponderance of point zero.

As the foregoing study leads one to the conclusion that the size of the heart could be compared with that found by Ungerleider and Clark in 1460 persons considered normal, who lived at altitudes close to sea level, it seemed to me necessary to continue this investigation.

The total number of cases which I report in this paper is 638, among which are included: 182 medical students between the ages of 17 and 30, who either were born in or had lived in Bogota for more than two years; 298 normal persons of both sexes, between the ages of 17 and 50, some of whom were natives of the plateau; others, persons who had lived in Bogotá for more than three months, and still others, persons who had been in the city for only a few days or weeks; and two military groups of 81 and 77 soldiers, respectively.

But I shall study carefully only the results obtained in 480 of these cases, because those obtained in the military groups differ from those of the other group, and open a way to further investigations. With reference to these 158 cases, I shall limit myself to making a brief summary of the results of this preliminary investigation.

The process carried out in the investigation was as follows, which, as can be seen, is the same as that followed by Ungerleider and Clark.

The anthropometric indexes were separated into groups and the transverse diameters of the heart, corresponding to each, were averaged by dividing the sum of these diameters by the number of cases. The index was averaged in a like manner, the answer being carried to the second decimal point for each case. Here are the results:

Anthropometric Index $\frac{\text{Weight in kilograms} \times 100}{\text{Height in Centimeters}}$	Diameters in Each Index	Number of Cases	Average Diameter of Each Index
19.11	83	1	83.0
23.27	105	1	105.0
24.41	185	2	92.5
25.32	100	1	100.0
26.43	617	6	102.8
27.15	395	4	98.7
28.44	1288	12	107.3
29.67	1275	12	106.2
30.43	1754	16	109.6
31.51	2271	20	113.5
32.45	5292	47	112.5
33.58	4088	34	120.2
34.57	5390	45	119.7
35.49	5408	45	120.1
36.48	5566	46	121.0
37.48	3964	32	123.8
38.56	3990	32	124.6
39.48	3506	27	129.8
40.52	3902	30	130.0
41.53	1950	15	130.0
42.50	1287	10	128.7
43.56	1533	12	127.7
44.23	953	7	136.1
45.19	556	4	139.0
46.22	565	4	141.2
47.32	719	5	143.8
48.19	144	1	144.0
49.40	154	1	154.0
50.72	283	2	141.5
51.71	283	2	141.5
52.24	145	1	145.0
56.37	302	2	151.0
57.92	130	1	130.0
	58183	480	

With these figures I plotted a graph, marking with a cross opposite each index the average corresponding to the transverse diameter. And with the value of the constant I computed the theoretic transverse diameter of each of the indexes. These values are marked by points joined together by a solid line (chart 2).

Chart 2 shows that the diameters obtained cluster in a manner similar to that of the observations made by Ungerleider and Clark.

---

[11] Ungerleider, H. E., and Gubner, R.: Evaluation of Heart Size Measurements, Am. Heart J. 24:494 (Oct.) 1942.

The constant found by them is exact, inasmuch as on averaging the 480 weights, heights and transverse diameters of my observations,

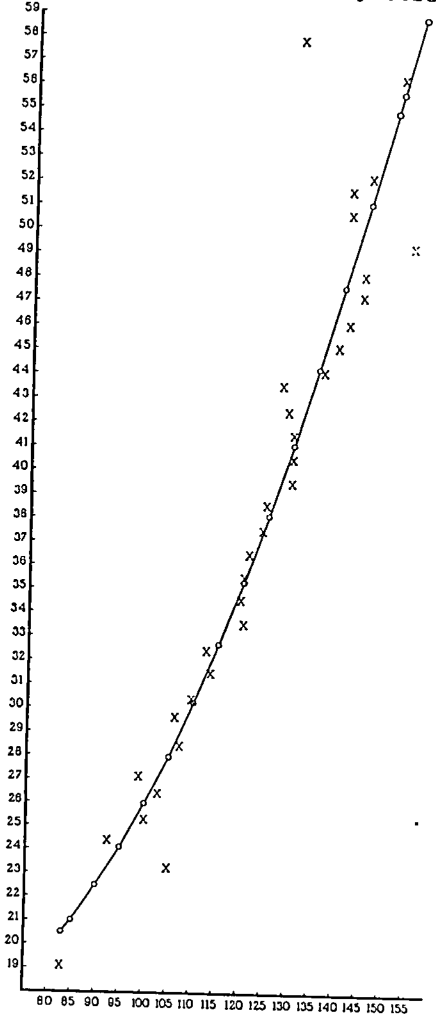

Chart 2.—Graph showing the constant established by Ungerleider and Clark (solid line) and the average corresponding to the transverse cardiac diameter of 480 normal persons examined in Bogotá marked with a cross opposite each index.

I obtained the figure 2.47, which is exactly the same as their average converted into kilograms and centimeters.

Data Obtained in Bogota

Average weight	60.42 kg.
Average height	165.96 cm.
Average transverse diameter	121.21 mm.

$$\frac{\text{Weight x 100,000}}{\text{Height x (Diameter)}^2} : \frac{60.42 \text{ x } 100,000}{165.96 \text{ x } (121.21)^2} = 2.47$$

Finally, Dr. Alfonso Esguerra Gomez, professor of physiology of the School of Medicine, produced the corresponding gaussian curve, with a modulus of 3, as the number of my observations was exactly one third of those presented by Ungerleider and Clark.

This gaussian curve helped to confirm that the cases of persons examined in Bogota fall into groups in a manner exactly similar to those of the United States. there being as a basis for comparison, in both, the theoretic prediction of the cardiac transverse diameter by the constant already mentioned (chart 3).

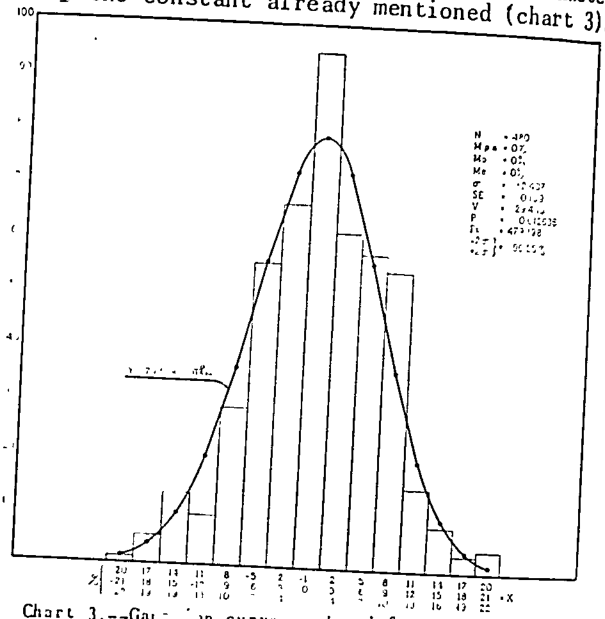

Chart 3.—Gaussian curve produced from 480 normal subjects examined in Bogotá, proving that they fall into groups exactly the same way as those of Ungerleider and Clark.

The arithmetic mean, the mode and the median all coincide at the zero point. Since, on the other hand, the standard error is 0.109, the chi square test gives a probability of 0.0126, the coefficient of variation is 29.446, the difference between the cases studied and the theoretic frequencies of the curve is 0.802, and the cases comprised between minus 2 sigma and plus 2 sigma are 462, or in other words 96.25 per cent, I consider that the conclusions arrived at are correct.

It can therefore be asserted that the average heart of the 480 persons examined in the city of Bogotá has the same transverse diameter, with relation to the anthropometric index, as that of the persons living at sea level. There is no increase, therefore, in heart size.

It only remains for me to make a brief commentary on the preliminary study conducted on the soldiers.

The first group examined comprised 77 men, with a minimum service of six months in the army and a residence in Bogotá of two years. The second was formed by 81 soldiers with six months' service in places close to sea level and who had come to the plateau twelve days before. As the histograms of both groups are so evidently equal, I have grouped them into one (chart 4).

Chart 4 indicates a deviation of plus 4 when compared with the other normal cases examined, and therefore it must be admitted that a slight cardiac hypertrophy exists in the soldiers. This enlargement cannot be attributed to their stay in the plateau, because the group of new arrivals demonstrated the same deviation and because the 480 persons not in the army are normal. Nor can one say that the arrival at the high plateau caused this hypertrophy, because there was no difference between the two groups and because among the remaining 480 whom I have just discussed, there were many who had arrived at the plateau a few days previously and the diameters of whose hearts were always within the same normal limits as those of the residents of Bogotá.

I believe, for these reasons, that it is a case of slight cardiac hypertrophy caused by the strenuous physical training to which the military men are subjected.

In order to arrive at a definite conclusion in this respect later on, roentgenologic examinations of the soldiers will be established in the army from the moment of enlistment to the time of their release. This will be done not only in Bogota but also in other cities close to sea level.

The fact that there is no enlargement of the heart in persons living in a city like Bogota, located 8,016 feet above sea level, does not mean that the heart does not work more and that it is free from hypertrophy in high altitudes. There are experimental facts, both in animals and in human beings, that prove the existence of this hypertrophy.

Van Liere[12] found that in guinea pigs exposed for at least 105 days to conditions similar to those prevailing in altitudes of 14,000 to 18,000 feet (4,240 to 5,490 meters) there is an increase in the heartweight/body weight ratio of the body of 55.8 per cent, and Takeuchi[13] has produced cardiac enlargement in cats by making them inhale mixtures of nitrogen and air. In human beings it has been experimentally demonstrated that from a height of 11,000 feet (3,350 meters) and up, chronic anoxia produces a decided increase in the size of the heart.

A. J. Kerwin,[3] by means of roentgenologic studies conducted on 273 persons living in Oroya, Peru, at 12,000 feet, showed that there is an increase of 11.5 per cent in the transverse diameter of the heart of the natives of this altitude, compared with the prediction tables of Ungerleider and Clark. Drs. Miranda and Rotta,[14] when comparing with these very prediction tables the results for 107 normal subjects at sea level and for 250 of Morococha (Peru) at 13,840 feet (4,220 meters), proved that in the natives of Morococha there is an increase in the cardiac transverse diameter that fluctuates between plus 11 and plus 30 per cent, with an average increase of 21 per cent.

If, in accordance with the roentgenologic studies, there is no increase in heart size in the city of Bogotá, neither does there exist cardiac hypertrophy without enlargement, as proved by the research carried out on 500 electrocardiograms by Dr. Alfonso Esguerra Gomez and by the research of Dr. J. H. Ordóñez,[15] conducted also by means of electrocardiograms, on 250 cases.

On the other hand, no pathologic variation is found in the pulse, blood pressure, number of respirations, respiratory capacity[16] or number of red blood cells in the residents of Bogotá.[17] All that can be observed are some phenomena in adaptation during the first few hours or days after arrival at the plateau. But shortly after arrival, and in many cases without any appreciable subjective symptoms, the organism adapts itself and continues functioning as at sea level.

SUMMARY

From the study of the transverse diameter of the heart by means of teleroentgenograms taken of 480 inhabitants of the city of Bogotá (altitude, 8,016 feet) the following conclusions are reached:

(a) When the values of the transverse diameter are correlated with the height and weight of the patient, they are identical with the values obtained by Ungerleider and Clark for persons living at sea level

(b) The constant $\dfrac{\text{Weight} \times 100{,}000}{\text{Height} \times (\text{Diameter})^2} = 13.83$, determined by the same authors in pounds and inches, is found to be, when converted into kilograms and centimeters, the same as the constant found when the figures obtained for the 480 persons examined in Bogotá were averaged according to weight, height and transverse diameters. The formula in kilograms and centimeters is:

$$\frac{\text{Weight} \times 100{,}000}{\text{Height} \times (\text{Diameter})^2} = 2.47$$

At 8,016 feet above sea level electrocardiographic signs of cardiac hypertrophy are not found, or abnormal variation of blood pressure, pulse, number of respirations, respiratory capacity or number of red blood cells.

In a preliminary study of 158 soldiers with six months' training in Bogota or in places near to sea level, a deviation of plus 4 was found on comparison of the transverse diameters of the heart of this group with the prediction tables based on the aforementioned constant.

It is supposed that the slight deviation observed in the soldiers is due to the intense physical training to which the soldiers are subjected.

Special Articles

TYPHOID IN THE LARGE CITIES OF THE UNITED STATES IN 1947

Thirty-Fourth Report

It has been customary in these reports to address a communication to the health officer of each of the cities requesting the number of deaths from typhoid, excluding paratyphoid, both among residents and among nonresidents. Although this practice was continued for 1947, it has been increasingly necessary to obtain from the state health departments the data on reallocations for residence, and, unfortunately, these could not be reconciled in all instances with the local reports. In such circumstances the figures provided by the state health departments have been accepted. A few local health officers seem to have no knowledge of how many deaths due to typhoid have occurred in their community, and this information can be secured only from the state health department. Some state departments have not completed the analysis of the statistical data, and the data in this article may not be complete in every detail. The possession of basic data seems paramount to an understanding of the problems of local health services.

* All deaths from typhoid were stated to be in nonresidents.
† One third or more of the reported deaths from typhoid were stated to be in nonresidents.

For most of the cities of 100,000 population or more the Bureau of the Census has no estimates of population for dates since 1940. There are figures for a few of these cities, based on special censuses or sample censuses for various dates since 1940. Special censuses were conducted for Long Beach, Los Angeles, Oakland and San Diego, Calif., in 1946. The Bureau of the Census has released a population estimate for Washington, D. C., as of July 1, 1946. Sample censuses were taken in 1944 for Detroit, Norfolk, Va., Portland, Ore., San Francisco, Seattle and Tacoma, Wash. (A special census was taken in San Francisco in August 1945.) Estimates of the civilian population of counties are available for March 1 and Nov. 1, 1943, based on registrations for war ration books 2 and 4. Some of the cities (Baltimore, Denver, New Orleans, New York, Norfolk, Philadelphia, Richmond, Va., St. Louis, San Francisco and Washington, D. C. are coterminous with their counties, and the figures given in the releases are city as well as county estimates. Since for the vast majority of cities no official figures are available for any date subsequent to that of the 1940 federal census, it has again been deemed advisable to employ the populations determined by this uniform tabulation. For those cities for which special census figures are available, corrections in rates have been shown in footnotes. In most instances there are no, or only minor, changes in the rates. In no instance has any rate been extended beyond the first decimal point, and it is realized that this practice creates a slight disadvantage for the extremely large cities which now have but a few deaths from typhoid, especially New York and Chicago, with only 2 deaths each, and Detroit, with only a single death and that among nonresidents.

no deaths among the residents. In four other cities (Atlanta, Ga., Kansas City, Mo., New Orleans and St. Louis) more than one third of the reported deaths were stated to have been among nonresidents. While in 1946 there was no city with a death rate in excess of 2.0, in 1947 there was one such city (Miami). Among cities with more than 1,000,000 inhabitants only Detroit records no death among residents.

The number of cities with no deaths due to typhoid during the past two or more years has increased from twenty-five in 1941 and forty-one in 1945 to a high of forty-nine in 1946 and again in 1947. Fort Wayne, Ind., continues to head the list, with no death in thirteen years. Two cities (Cambridge and Lynn, Mass) also record no deaths in ten or more years. Duluth, Minn., Springfield, Mass., and Yonkers, N. Y., have clear records for nine years; Canton, Ohio, Erie, Pa., Grand Rapids, Mich., and Tulsa, Okla., for eight years. South Bend, Ind., reports no death due to typhoid among residents for twelve years, Fall River, Mass., none for eleven years and Hartford, Conn., none for nine years.

* One third or more of the reported deaths from typhoid were stated to be in nonresidents.

† All deaths from typhoid were stated to be in nonresidents.

‡ Incomplete data.

The New England cities (table 1) (population 2,579,152) which set a new all-time record in 1946, with no deaths from typhoid, did not even maintain first place in 1947 and were outranked by the Middle Atlantic and East North Central cities. The rates in the latter two groups were 0.05 each, while the New England group reports a rate of 0.08. Ten of the New England cities record no death in 1947. Fall River and Hartford report 1 death each among nonresidents. In Boston and Providence, R. I., the single death each was among residents. The group as a whole reports 4 deaths, of which one half were among nonresidents. There have been only 7 deaths in the New England cities during the past four years, 2 each in Boston and Providence, 1 each in Fall River, Hartford and New Bedford, Mass. While in 1940 one half of the eighteen cities which recorded no deaths from typhoid during a two year period were to be found among the New England cities, in 1947 only about one fifth (ten among forty-nine) were from this group. The New England cities possess an excellent record, but there is a continued significant trend for other cities to attain the high standards set by this group.

Sixteen of the large Middle Atlantic cities (population 13,129,185) (there were only eight in 1941, thirteen in 1945) report no death from typhoid in 1947 (table 2). *These cities report the lowest group rate for 1947, followed by a fraction when computed to the third decimal, by the cities of the East North Central States.* Albany, N. Y., Buffalo, Elizabeth, N. J., Erie, Pa., Jersey City, N. J., Paterson, N. J., Reading, Pa., Syracuse, N. Y., Trenton, N. J., and Yonkers have maintained their ranking, with no typhoid death for three or more years. No death has occurred in Camden and Newark, N. J., during the past two years. Pittsburgh, Rochester, N. Y., Scranton, Pa., and Utica, N. Y., have been added to the honor roll. New York records a new low mark, with only 2 deaths. The previous low was in 1943, with 4 deaths. In 1946 there were 8 deaths. An interesting report on an outbreak in New York attributes 6 cases to the carelessness of 1 typhoid carrier. The latter had been under observation for fourteen years. She concluded that, since everything had gone well for this long period of time, she was no longer a carrier. She therefore arranged a dinner at her home, to which were invited members of the family. Her own children had been protected against typhoid soon after the discovery of her carrier state, and some of them had been reimmunized since. However, an unprotected son-in-law and daughter-in-law partook of the dinner. Typhoid developed in both within two weeks. The daughter-in-law exposed a sister during her acute illness, and the latter had typhoid about two weeks after exposure. She, in turn, exposed 3 of her children, all of whom became sick with typhoid. Thus, 6 cases were attributable to the carelessness of a carrier. Philadelphia reports 4 deaths, 3 among residents. All 6 deaths recorded in

this group of cities occurred in the two largest cities, New York and Philadelphia.

The rate (0.37) for the South Atlantic cities (table 3) (population 2,727,985) is higher than the low rate for 1944 (0.22), but is lower than the rate for 1946 (0.44) and that for 1945 (0.62). In these cities there occurred 10 deaths in 1947 (6 among residents) and 12 in 1946 (9 among residents). Six cities (Charlotte, Jacksonville, Fla., Norfolk, Tampa, Washington and Wilmington, Del., are on the honor roll, and it is stated that the 3 deaths in Baltimore occurred among nonresidents. Charlotte has been included in the group for the sixth time; however, for the purposes of adequate comparison, the figures for this city have been omitted in calculating rates for the group as a whole. Washington reports no death in 1947, in comparison with 6 in 1946, 5 among residents (there were 2 deaths in 1945, 4 in 1944, 1 in 1943). Richmond, with no death in 1946, reports 1 among residents in 1947. Five cases occurred in a single household, the first case being that of the father, who worked for the city as a sewer cleaner. Atlanta, with no death in 1946, records 2 in 1947, 1 among residents. Miami, with no death in 1946, reports 4 in 1947, all among residents.

‖ Special census for 1944 gives rate of 0.1† for 1941-1945 for San Diego.

¶ Special census for 1945 gives rate of 0.1‡ for 1945 and 0.4 for 1947 for San Francisco.

The East North Central cities (population 9,386,378) are in virtual tie with the Middle Atlantic cities for first place (rate 0.05). They held first place in 1945 and back in 1941 and 1938. Sixteen (fifteen exclusive of Gary) of the cities in this group (Akron, Canton, Cincinnati, Cleveland, Columbus, Dayton, Ohio, Evansville, Ind., Flint, Mich., Fort Wayne and Gary, Ind., Grand Rapids, Mich., Milwaukee, Peoria, Ill., South Bend and Toledo and Youngstown, Ohio) report no death from typhoid in 1947 (table 4). Gary was added to this group in 1940, but figures for this city have been omitted in determining rates for the group as a whole. The number of deaths due to typhoid decreased from 6 in 1946 (33 in 1940) to 5 in 1947, a new low (the rate from 0.35 in 1940 and 0.06 in 1946 to 0.05 in 1947). Thirteen cities record no death from typhoid during 1946 and 1947 (table 9), Fort Wayne none for thirteen years (the longest honor record of any city), Canton and Grand Rapids none for eight years and Evansville and Gary none for seven years. Cleveland has been on the honor roll for three years. Detroit records no death among residents, 1 among nonresidents. Chicago and Indianapolis report 2 deaths each all among residents.

The six cities (table 5) in the East South Central group (population 1,286,747) show a decrease in the death rate (0.23 in 1947, 0.54 in 1946 and 0.70 in 1945). This marks a new low record for these cities, the previous low being 0.31 in 1944. This group, which held the highest group rates in 1946 and 1945, is in fourth place in 1947. Of 3 deaths, 2 are stated to have occurred among nonresidents. Thus, the 1 death from typhoid in Louisville, Ky., is the only death among residents in these six cities. The 2 remaining deaths (both in Memphis, Tenn.) were among nonresidents. Four cities (Birmingham, Ala., Chattanooga, Knoxville and Nashville, Tenn.) report no deaths among either residents or nonresidents and appear on the honor roll. Chattanooga has no data regarding deaths among nonresidents, and the state health department reports that it will be several months before such information is ready for release. With this uncertainty regarding data, it is stated that there has been no death in Chattanooga for six years.

* Forty-seven without Charlotte and Gary.

† Number of years with no deaths due to typhoid.

The West North Central cities (population 2,716,484) show an increase in the number of deaths, from 2 in 1946 to 7 in 1947 (table 6); 5 of the 7 were among residents. The death rate increased from 0.07 in 1946 (it was 0.11 in 1943, 1944 and 1945) to 0.26 in 1947. This group of cities is now in fifth place. Six cities (Duluth, Kansas City, Kan., Minneapolis, Omaha, St. Paul and Wichita, Kan.) record no death. Omaha reports only 2 deaths (1 each in 1945 and 1946) in seven years. There has occurred no death from typhoid in Duluth for the past nine years (table 9), none in Minneapolis for six years and none in Wichita for five years. After a period of seven years without a death, Des Moines records 1 among residents in 1947. After a period of five years with no death among residents, Kansas City, Mo., reports 2 among residents and 1 among nonresidents in 1947. St. Louis records `3 deaths, 2 among residents.

* Charlotte, Gary and Sacramento omitted.

The eight cities of the West South Central group (table 7) (population 2,048,692) report the same number of deaths (8) as for 1946. The rate of 0.39 in 1947 is in contrast to the rate of 2.00 in 1940. Notwithstanding this continued reduction, the rate for this group of cities is the highest for all groups (followed closely by the South Atlantic cities with a rate of 0.37). Of the 8 deaths in the West South Central cities, 5 were among nonresidents (2 of 8 in 1946). The 3 deaths among residents represents a new low, the previous low of 4 deaths having occurred in 1945. Four cities (Dallas and El Paso, Texas, and Oklahoma City and Tulsa, Okla.) record no death in 1947. Tulsa reports no death for eight years. Fort Worth and San Antonio record 1 death each among nonresidents. It is stated that of the 5 deaths in New Orleans, 3 were among nonresidents. Houston, Texas, reports 1 death among residents.

1946	38,060,662‡	62	0.16
1947	38,060,662‡	57	0.15

* The following fifteen cities are omitted from this table because data for the full period are not available: Canton, Chattanooga, Dallas, Fort Wayne, Jacksonville, Knoxville, Long Beach, Miami, Oklahoma City, South Bend, Tampa, Tulsa, Utica, Wichita and Wilmington.
† Data for Fort Worth lacking.
‡ Census figures for 1940 were used.

The eleven cities (excluding Sacramento, Calif.) in the Mountain and Pacific states (table 8) (population 4,186,039) report an increase of 1 death (13 in 1946 and 14 in 1947). There were only 5 deaths in 1944. The rate has increased from 0.17 in 1945 to 0.31 in 1946 and to 0.33 in 1947. Sacramento has again been omitted in calculating the total number of deaths and the rates. Six of the Mountain and Pacific cities (Denver, Long Beach, Oakland, Sacramento, Spokane and Tacoma) report no death from typhoid in 1947. There were *nine cities on the honor roll in 1944*, eight in 1945 and five in 1946. Long Beach and Oakland have reported no death in four years. Salt Lake City records no death among residents for six years and San Diego *none* for five years. Each of these two cities reported 1 death among nonresidents in 1947. San Francisco reports 3 deaths among residents and Portland and Seattle 1 each. Of 7 deaths in Los Angeles, it is stated that 3 occurred among nonresidents. It is also stated that in 2 of the 4 deaths among residents, the source of infection was outside the city. In 1946 there were 5 deaths in Los Angeles, 4 among residents.

THE HONOR ROLL

The number of cities with no death from typhoid has increased from sixty to sixty-five (table 11). Charlotte, Gary and Sacramento, not included in the group of ninety-three cities, also report no death. This is by far the best showing, and there remain only two cities with a rate of 1.0 or more. Forty-seven cities (forty-nine with Charlotte and Gary) record no death from typhoid in 1946 and 1947 (table 9). It is again emphasized that nine cities (Baltimore, Detroit, Fall River, Fort Worth, Hartford, Memphis, Salt Lake City, San Antonio and San Diego) in the first rank would appear in the honor roll were they not charged with deaths among nonresidents.

TABLE 13.—*Total Typhoid Death Rate per Hundred Thousand of Population for Ninety-Three Cities According to Geographic Divisions*

		Deaths from Typhoid		Typhoid Death Rates				
	Population*	1947	1946	1947	1946	1941-1945	1936-1940	1931-1935
New England...........	2,579,152	4	0	0.08†	0.00	0.14	0.39	0.70
Middle Atlantic.........	13,129,185	6	14	0.05	0.11	0.17	0.43	0.80
South Atlantic..........	2,727,985	10	12	0.37†	0.41	0.54	1.14	2.70
East North Central....	9,386,378	5	6	0.05	0.06	0.16	0.53	0.75
East South Central....	1,286,747	3	7	0.23†	0.54	0.57	2.54	4.81
West North Central....	2,716,484	7	2	0.26	0.07	0.16	0.60	1.24
West South Central....	2,048,692	8	8	0.39†	0.39	0.89	3.09	5.36
Mountain and Pacific..	4,186,039	14	13	0.33†	0.31	0.23	0.60	0.88

* Census figures for 1940 were used.

† One third or more of the reported typhoid deaths were stated to be in nonresidents.

For the seventy-eight cities (table 12) for which data are available since 1910 there occurred 53 deaths from typhoid in 1947 (54 in 1946, 80 in 1945 and 66 in 1944). The rate of 0.15 (to second decimal) remains the same as that of 1946. For the ninety-three cities the number of deaths in 1947 is 57 (62 in 1946 and 87 in 1945). The rate of 0.15 marks a new all-time low.

Table 13 shows the number of deaths for each of the past two years in each group of cities. It also shows the rates for 1946 and 1947, the quinquennium 1941 to 1945 and the two preceding five year periods. The continued reduction in rates for all groups is impressive. Unfortunately, this may be influenced slightly by the effort of some communities to unload the deaths which occur within the area on neighboring cities or states or other countries. For 1947 the health officers report no significant outbreaks. Improvement remains general throughout the country, and typhoid as a cause of death in these cities is fast approaching the vanishing point.

CANCER OF THE HEAD AND NECK

HAYES MARTIN, M.D.
Attending Surgeon, Memorial Hospital
New York

This article is the fourteenth of a series to be published by the American Medical Association in cooperation with the American Cancer Society. The series is designed to aid in the early diagnosis of cancer and thereby to gain more effective results in treatment.

I. CANCER OF THE MOUTH

The term cancer of the mouth is commonly used to define those malignant tumors which arise in the mucous membranes of the oral cavity beginning anteriorly at the mucocutaneous junction of the lips and extending posteriorly to the level of the free edge of the soft palate, the tonsil and the base of the tongue. Cancer of the mouth may be divided into several varieties based on the anatomic site of the origin of the tumor; namely, lip, cheek, gum, floor of mouth, tongue, palate and tonsil. From the practical point of view growths arising in these different areas present distinct clinical problems especially with regard to treatment, and in the evaluation of an individual case it is essential that the primary site of origin of the tumor be definitely determined.

ETIOLOGY

Cancer of the mouth comprises about 4 per cent of all human cancer, and about 70 per cent of all cancer in the upper respiratory and alimentary tracts. Males are affected about five times as frequently as females (cancer of the lip and floor of the mouth, 98 per cent in males; cancer of the tongue, gum, tonsil, palate and cheek, 80 to 90 per cent in males). Intraoral cancer is mainly a disease of middle and old age, although it may occur in the young and even in infants.

Causative Factors.—The actual cause of cancer in any part of the body has not been established, but several forms of chronic irritation are known to be important contributing factors in the causation of cancer of the mouth. The form of chronic irritant is of less importance than its chronicity.

In cancer of the lower lip overexposure to sunshine over a period of many years is a significant etiologic factor, and the disease is found most often among outdoor workers such as farmers and sailors. A frequent source of chronic irritation within the mouth is syphilitic glossitis. About one third of all male patients with cancer of the tongue have chronic syphilis, as contrasted with about 4 per cent of syphilis in males of similar age groups without cancer of the tongue. Chronic glossitis and stomatitis may also be due to nutritional deficiencies (avitaminosis B).

Tobacco, especially smoking, can be demonstrated statistically to be an important causative factor. The incidence, especially of excessive smoking, is higher in persons with cancer of the mouth than in the normal. The so-called pipe smoker's cancer of the lip is not as frequently seen now as formerly, when clay pipes were in common use. Leukoplakia of the oral mucous membranes occurs as a response of the tissue to chronic irritation and is ofter found to precede or to be associated with cancer. These two conditions have a common etiology so far as chronic irritation is concerned. The etiologic significance of chronic irritation from sharp or broken teeth and ill-fitting dentures has undoubtedly been greatly overemphasized.

PATHOLOGY

The most frequent histologic type of cancer of the mouth is epidermoid carcinoma (about 90 per cent). This is to be expected, since malignant tumors of the oral cavity for the most part arise from mucous membrane of the squamous variety. Adenocarcinoma is occasionally found in this portion of the upper part of the alimentary tract and is most often seen in the palate; such a morphologic type of cancer has its origin either from minor salivary glands or from mucous gland tissue. Melanoma, spindle cell sarcoma, malignant mucoepidermoid tumors and malignant lymphoma occur, though rarely, in the mouth.

About 75 per cent of oral cancer is well differentiated (grades 1 and 2) and the more malignant (less differentiated) varieties of epidermoid carcinoma are more frequently found in the posterior part of the oral cavity (tonsil and base of tongue). Other highly malignant cancers, such as anaplastic and transitional cell carcinoma, also have an affinity for structures in the posterior oral cavity, particularly in the tonsillar region.

SYMPTOMS, MORBID ANATOMY AND CLINICAL COURSE

The first or early subjective symptoms of cancer of the mouth vary according to the location of the primary lesion. When this disease occurs on the lower lip, the first symptom noted by the patient is always the presence of the growth, since this portion of the anatomy is under daily self observation (fig. 1). Within the oral cavity, especially in the anterior portions of the tongue, floor of the mouth or the cheeks, the cancer is usually discovered by the tactile sense of the tongue, or less frequently there is pain or tenderness in the ulcer which has become slightly inflamed.

Further back in the oral cavity (tonsil, base of tongue and palate), where tactile and pain sensations are less acute, the primary lesion rarely produces any symptoms in its early stages and the growth usually reaches the size of 2 to 3 cm. before subjective manifestations arise. At this stage of the disease the lesion becomes infected, so that the first symptom of the local growth is slight pain on swallowing or speaking. In this locality, moreover, the tumor may remain silent, and in such cases the first symptom will be the discovery by the patient of an enlarged (metastatic) lymph node in the neck.

Early cancer of the mouth is characterized objectively by the appearance of an indurated plaque or ulcer which infiltrates the mucous membrane for a varying distance. On examination, the primary lesion of cancer of the mouth may appear as a small, smoothly granular ulcer, 2 to 3 mm. in diameter; a fissured patch of leukoplakia; a slightly ulcerated, papillary tumor; an excavated ulcer with indurated edges, or a necrotic ulcer covered with slough. The most common and characteristic picture is a coarsely granular ulcer with indurated, raised, rolled edges (figs. 2 and 3). Although the lesion is usually slightly tender, this characteristic is obviously not as pronounced as is found in benign inflammatory ulcers of similar size.

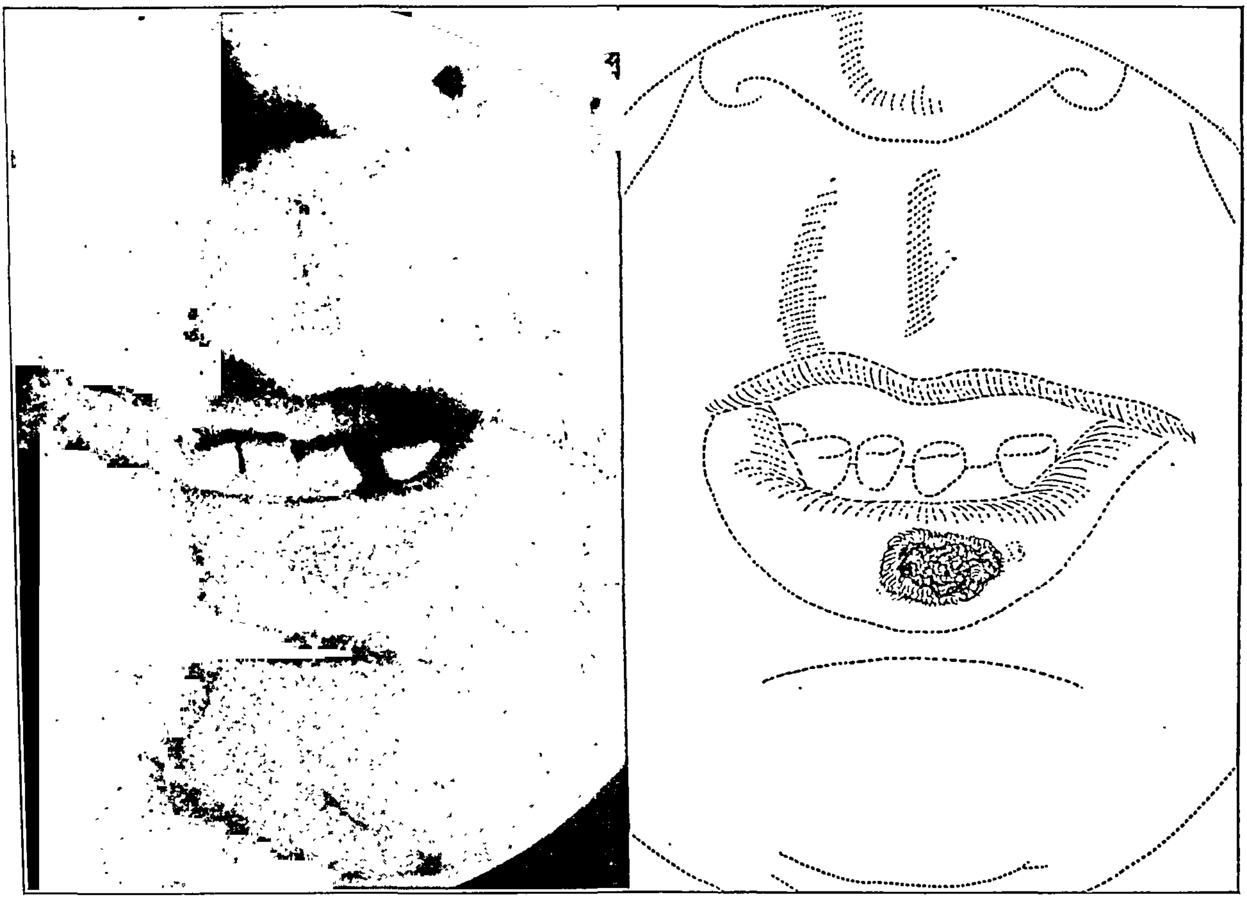

Fig. 1.—Cancer of the lip. Cancer of the lip in a moderately early stage presenting as an indolent, granular, indurated ulcer with raised, rolled edges. It is neither tender nor painful. In such cases the patient has been aware of the lesion since its inception.

As cancer of the mouth progresses, ulceration and deep infiltration become more apparent, accompanied by extensive secondary infection, and only at this time do pain and disability become marked. The later stages are characterized by steadily increasing infiltration of the tongue, the cheeks, the floor of the mouth, the tonsil and the palate, and often, depending on the site of origin of the primary growth, invasion and erosion of the mandible and maxilla occur. As the normal structures are invaded and destroyed by the growth, the movements of the tongue and jaws are restricted (trismus) and speech becomes less distinct. The swallowing of food and drink is often both difficult and painful, and in some cases the patient may not even be able to swallow his saliva, which must then be spat out (salivation). In other cases, the expanding growth and edema may encroach on the lumen of the pharynx or larynx to cause both dysphagia and dyspnea. Repeated hemorrhages may result from the erosion by cancer of large blood vessels. Death in uncontrolled cancer of the mouth usually occurs from one or more of the following complications: sepsis, malnutrition and dehydration, pain, hemorrhage, respiratory obstruction and metastasis.

Metastasis.—The cervical lymph nodes may be involved by metastasis early in the course of the disease, while the primary lesion is only a few millimeters in diameter, but such spread almost invariably takes place during the advanced stages. At first there is barely discernible enlargement of one or more lymph nodes, but as the disease progresses, the metastatic cervical mass, sometimes multiple and bilateral, may reach a size of 10 to 15 cm. in diameter. Such cancerous lymph nodes frequently become infected, producing bulky, fluctuating, liquefied abscesses. If the malignant growth in the mouth and in the neck is not controlled and if the patient survives long enough, metastasis almost invariably occurs to some viscus below the clavicle, such as the lungs or the liver, or to the bones.

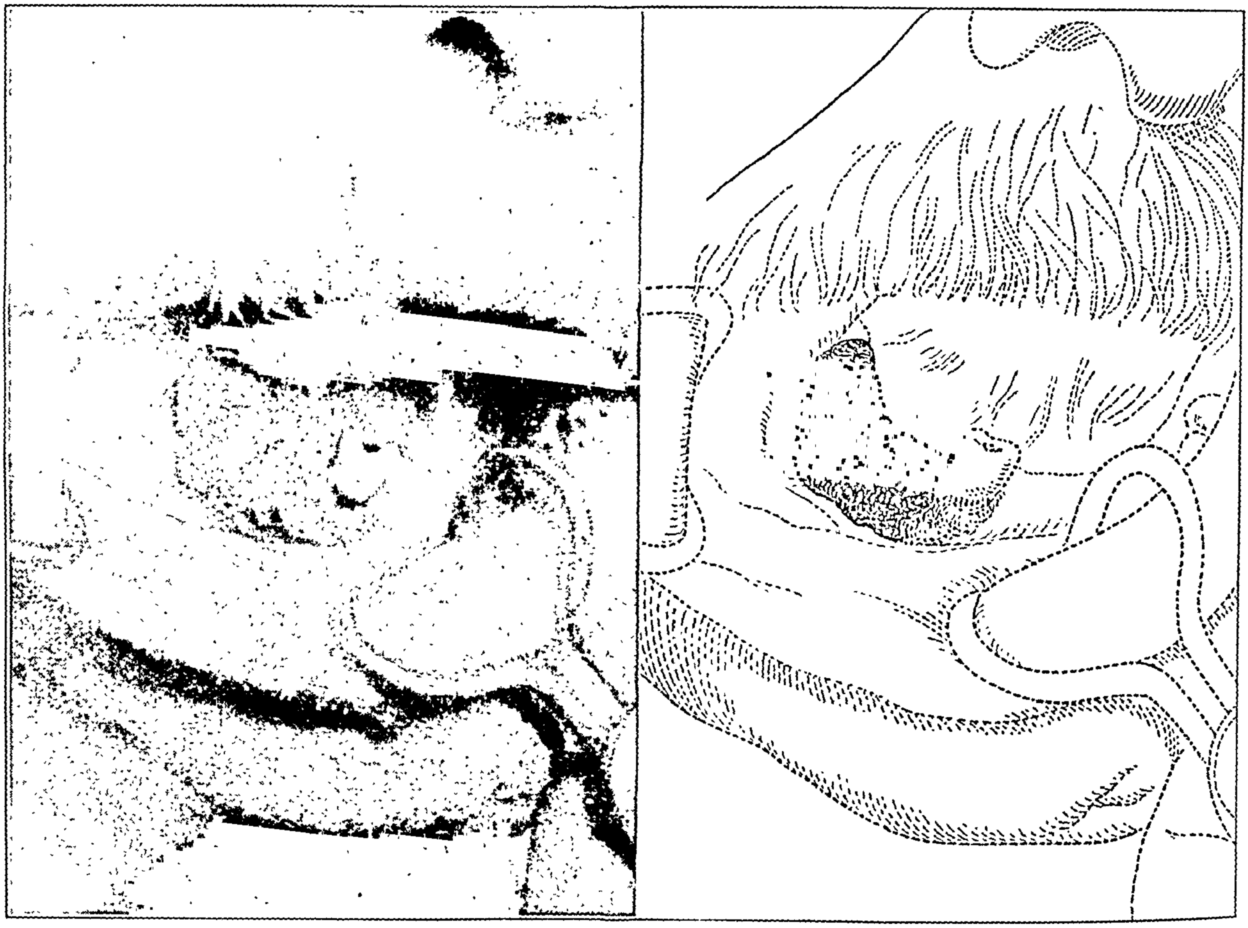

Fig. 2.—Cancer of the gum. The growth is a fungating, coarsely granular tumor of the right lower gum. The presence of the single tooth in the edge of the lesion suggested to the patient that the growth was due to some dental disorder, and he first consulted his dentist.

DIAGNOSIS

It can be stated without any hesitancy that cancer of the mouth is more serious and more important to the patient than any other condition with which it might be confused. Therefore, in any suspicious lesion of the mouth, the physician should consider cancer first, and should rule out such a possibility before waiting "to see what happens" or proceeding with treatment on the basis of a benign diagnosis. If the possibility of a malignant growth is considered at the beginning, few harmful errors in diagnosis will be made.

One significant fact to establish in the history of patients with suspected cancer of the mouth is that the lesion is chronic and progressive. If the patient can recall that the abnormality has been present for several weeks or months and is steadily increasing in extent, this fact alone suggests a diagnosis of malignant tumor. Nevertheless, failure to establish a history of long duration of symptoms is of negative value only, for it is not uncommon that a patient suffering from a cancerous growth several centimeters in diameter will consult a physician insisting that his symptoms appeared only a day or two previously. It is curious that many persons are so unobservant of purely objective symptoms.

Adequate examination of the mouth cavity is not difficult provided the physician has proper illumination, a finger cot or rubber glove, and a tongue depressor. Palpation of the buccal vestibule, the floor of the mouth, and the tongue should be made in all cases. The only region of the oral cavity not accessible to direct vision is the base of the tongue. This area is readily palpable, however, and if the symptoms seem localized to this region, confirmation of the presence of a lesion may require visualization with a throat mirror.

Differential Diagnosis.—Cancer of the mouth is often mistakenly diagnosed as one of the following benign lesions: Vincent's ulcer (trench mouth), herpes, trauma (biting the tongue or cheek) and gumma. If a diagnosis of an acute inflammatory or traumatic condition is made, such a benign diagnosis should not be persisted in for more than two weeks before a biopsy is made. All these benign lesions should respond to simple measures within that period. Smears and cultures do not rule out the possibility of cancer.

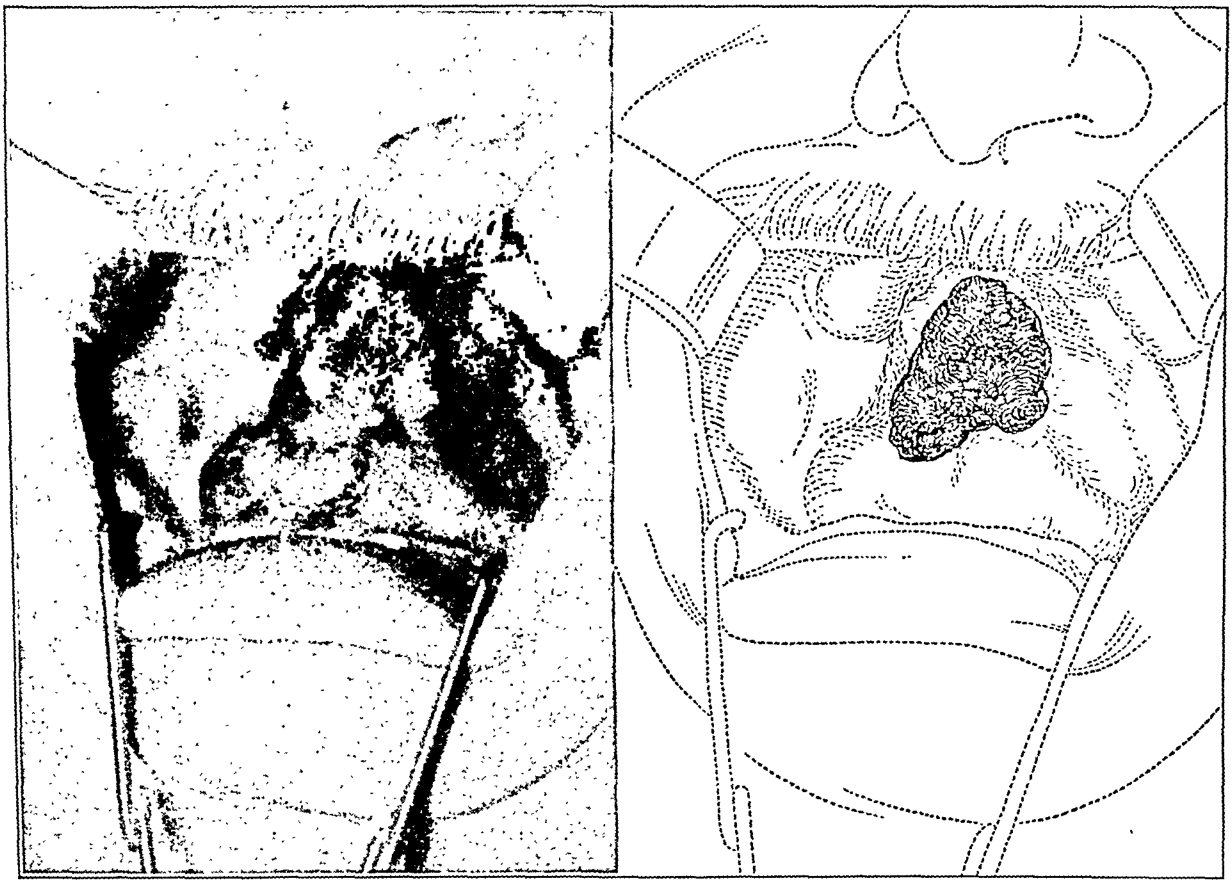

Fig. 3.—Cancer of the floor of the mouth. The lesion is an ulcerated, granular ulcer beginning in the floor of the mouth and extending up onto the undersurface of the tongue. The patient was an elderly dentist who had worn complete upper and lower dentures for many years. He believed the ulcer to be due to an irritation from his lower dental plate and spent several months adjusting the fit of the plate before consulting a physician, who made a diagnosis of cancer.

A gumma or other ulcerated syphilitic lesions are exceedingly rare as compared with cancer of the mouth. A chronic syphilitic ulcer cannot be clinically distinguished from cancer of the mouth, but cancer of the mouth is between three and four hundred times as frequent as a syphilitic ulcer or gumma of the mouth. In cancer of the tongue in males, about 1 in 3 patients will be found to have syphilis, and therefore a positive serologic reaction for syphilis should never be depended on to exclude the presence of cancer. Tuberculous ulcers of the oral mucous membranes are much more frequent than syphilis, but, nevertheless, are rare as compared with cancer.

Biopsy.—An unqualified diagnosis of cancer even in advanced cases can be made only by the pathologist. Lacking microscopic examination of tissue, a diagnosis can be no more than "tentative" or "clinical." It is the responsibility of the examining physician to determine whether the lesion clinically looks enough like cancer to warrant the taking of a specimen for biopsy.

TREATMENT

In the treatment of cancer of the mouth the same methods are employed as for malignant neoplastic disease anywhere about the body; namely, surgical treatment and roentgen radiation or radium therapy—either alone or in combination. These methods should be considered as complementary rather than competitive.

In some anatomic varieties of cancer of the mouth, such as cancer of the lip and gum, surgery alone is preferable in most cases as the primary form of treatment, although supplementary radiation therapy is often indicated should there be postoperative recurrence. In cancer of the mucosa of the cheek, anterior portion of the tongue, floor of the mouth or palate (figs. 4, 5 and 6) the selection of either method alone or in combination depends on the particular features in the individual case. For cancer of the tonsil and base of the tongue (fig. 7) a combination of roentgen therapy and interstitial radiation rather than surgical treatment is indicated.

In the treatment of metastasis to cervical nodes, neck dissection is the method of choice in all operable cases. In those situations where cervical metastases are inoperable, or in others where operation cannot be performed because of the presence of an inoperable primary lesion, a program of radiation therapy should be employed. Radiation therapy is often successful in the treatment of inoperable cervical metastatic cancer or in postoperative recurrences.

PROGNOSIS AND END RESULTS

Frequently the treatment of early cancer of the mouth is delayed because the physician or the patient or his family believes the disease to be incurable. A

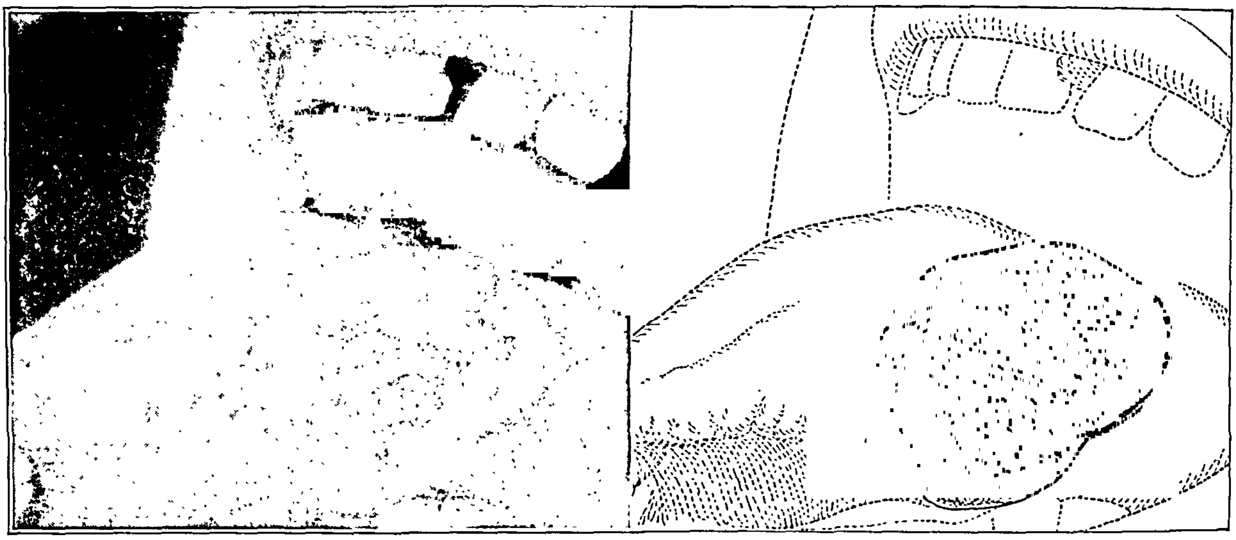

Fig. 4.—Cancer of the tongue. The growth arises in the middle of the left edge of the tongue and presents as a raised, granular, indurated ulcer. At the edge the nonulcerated mucous membrane is raised and rolled.

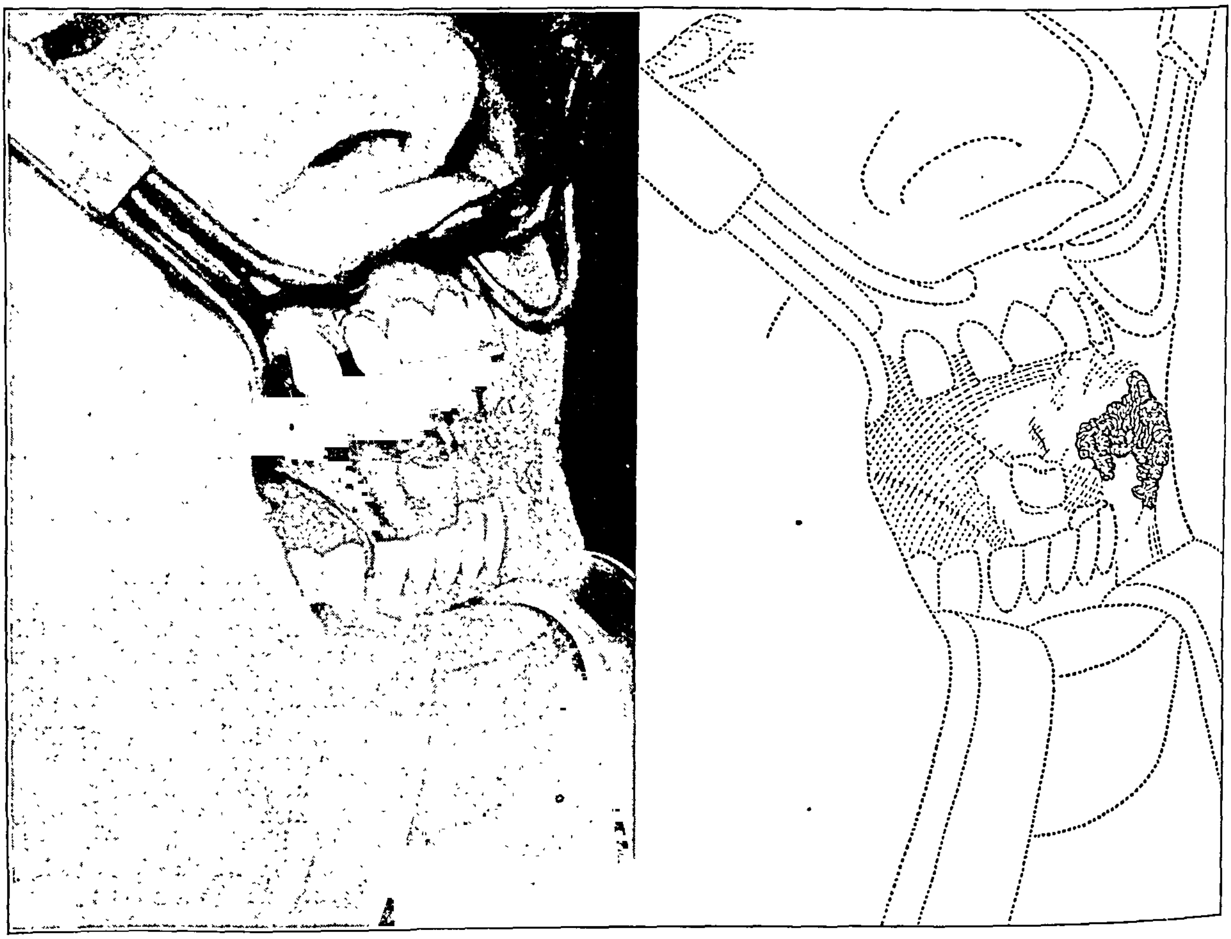

Fig. 5.—Cancer of the mucosa of the cheek. Just back of the labial commissure on the left, there is a flat, granular, nodular, indurated ulcer. The patient has been aware of the roughness of the cheek for several months. The lesion is neither tender nor painful.

Gallup poll taken in 1945 revealed that one United States citizen in four thinks that cancer is incurable. Strangely enough, some physicians hold almost as gloomy an opinion concerning the curability of this disease. Cancer of the mouth is among the more favorable varieties of malignant neoplastic disease from the standpoint of treatment and cure. Growths in this area can be discovered in their early stages. Even in the advanced stages, the disease frequently remains localized to accessible areas in the mouth or cervical lymph nodes, and cures can be accomplished in a fair percentage of these cases.

As with all serious diseases, the prognosis for cure depends more than anything else on early diagnosis and prompt treatment. In table 1 are listed a few recently calculated five year cure rates for the various anatomic forms of cancer of the mouth obtained at one hospital. It will be noted that when the primary lesions are less than 2 cm. in diameter, the chance of cure is almost double that which can be obtained in all comers when the more advanced cases are included.

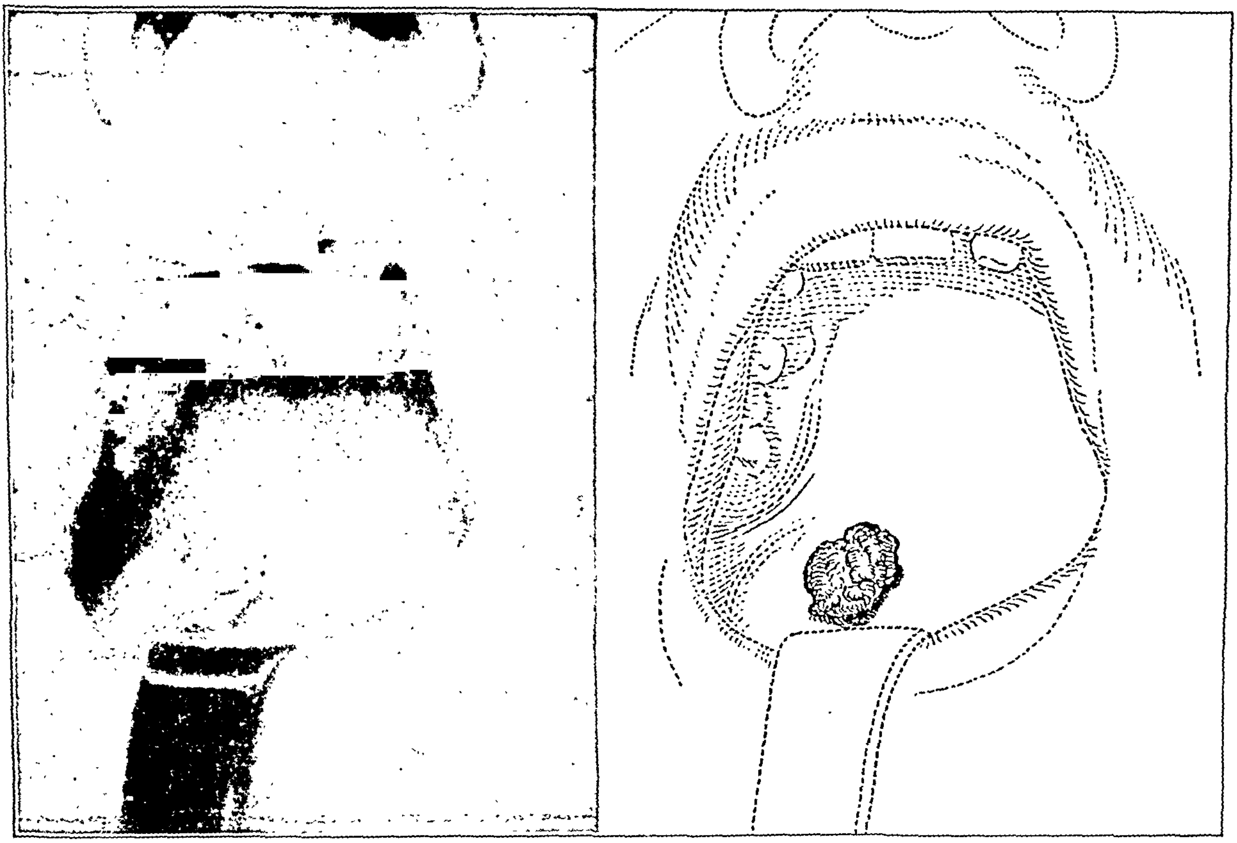

Fig. 6.—Cancer of the palate. On the right soft palate there is a raised, papillary, slightly pedunculated lesion.

Table 1.—*Five Year Cure Rates in Cancer of the Mouth* *

Site of Primary Lesion of Cancer	Five Year Cure Rate in All Cases (All-Comers, Both Early and Advanced)	Five Year Cure Rate in Early Cases (Primary Lesions Less than 2 Cm.)
Lip	70	86
Tongue	28	55
Floor of mouth	25	50
Mucosa of cheek	29	60
Palate (hard and soft)	31	57
Gums	26	38
Tonsil	18	40

II. CANCER OF THE NASOPHARYNX AND PHARYNGEAL WALL

Anatomically the pharynx is a funnel-shaped, hollow tube which extends from the base of the skull to the level of the lower border of the cricoid cartilage. Malignant tumors which arise in the walls of this structure above the level of the soft palate (and posterior to the nasal cavity) are properly classified as cancer of the nasopharynx. Growths which arise in the pharyngeal mucosa below the level of the soft palate but above the lower border of the cricoid cartilage (excluding the palatine tonsil, base of the tongue, and the extrinsic larynx) may be classified as cancer of the pharyngeal wall (fig. 8). Since the symptoms, morbid anatomy, clinical response to treatment, and complications of nasopharyngeal cancer differ markedly from those of pharyngeal wall cancer, growths in these two localities are best described under separate headings.

CANCER OF THE NASOPHARYNX

Cancer of the nasopharynx, although not the most frequent, is one of the most malignant growths of the upper respiratory and alimentary tracts. The symptoms are deceptive—that is, the primary growth in the nasopharynx often remains silent and the disease first appears in the form of metastasis to the cervical lymph nodes; in other cases, the symptoms of the disease in the nasopharynx are referred only to the ear and the attention of the examiner may be drawn to the external auditory meatus. Occasionally, the symptoms of the primary growth may be so overshadowed by metastases that many of the patients undoubtedly die of widely disseminated cancer with the actual site of the primary lesion in the nasopharynx unsuspected.

ETIOLOGY OF CANCER OF THE NASOPHARYNX

Nasopharyngeal cancer makes up about 0.2 per cent of all malignant growths and a little more than 3 per cent of all cancers of the upper alimentary and respiratory tracts. The disease sometimes occurs in children and more often at ages below 30 than any other malignant tumor in the head and neck. This anatomic variety of cancer is encountered more frequently in males (80 per cent) than in females.

Cancer of the nasopharynx is somewhat unique in that there is a distinct racial susceptibility of Orientals (especially the Chinese) to the disease. This susceptibility is even found in Orientals born in the United States, which suggests that the tendency is one which is racially inherited rather than due to environmental factors.

PATHOLOGY OF CANCER OF THE NASOPHARYNX

Since cancer of the nasopharynx arises most commonly at the site of the pharyngeal tonsil, it is natural that highly anaplastic epidermoid carcinoma and lymphosarcoma should make up a large proportion of growths in this region. Malignant tumors originating in a minor salivary gland are occasionally encountered in the nasopharynx; chondrosarcoma, myxosarcoma and chordoma occur but rarely in this locality. Although numerous reports have appeared dealing with lymphoepithelioma, its actual existence as a distinct morphologic entity is highly disputed. Some observers even feel that there is no justification for the term.

SYMPTOMS, MORBID ANATOMY AND CLINICAL COURSE OF NASOPHARYNGEAL CANCER

It is characteristic of this disease that the primary lesion in the nasopharynx causes relatively few if any symptoms in the early stages. The nasopharynx is a cavity with rigid walls and is wider than the combined lumens of the two nasal cavities, so that obstruction to breathing will not occur until the tumor has become bulky. If the growth arises at the orifice of the eustachian tube, the local symptoms are referred only to the ear.

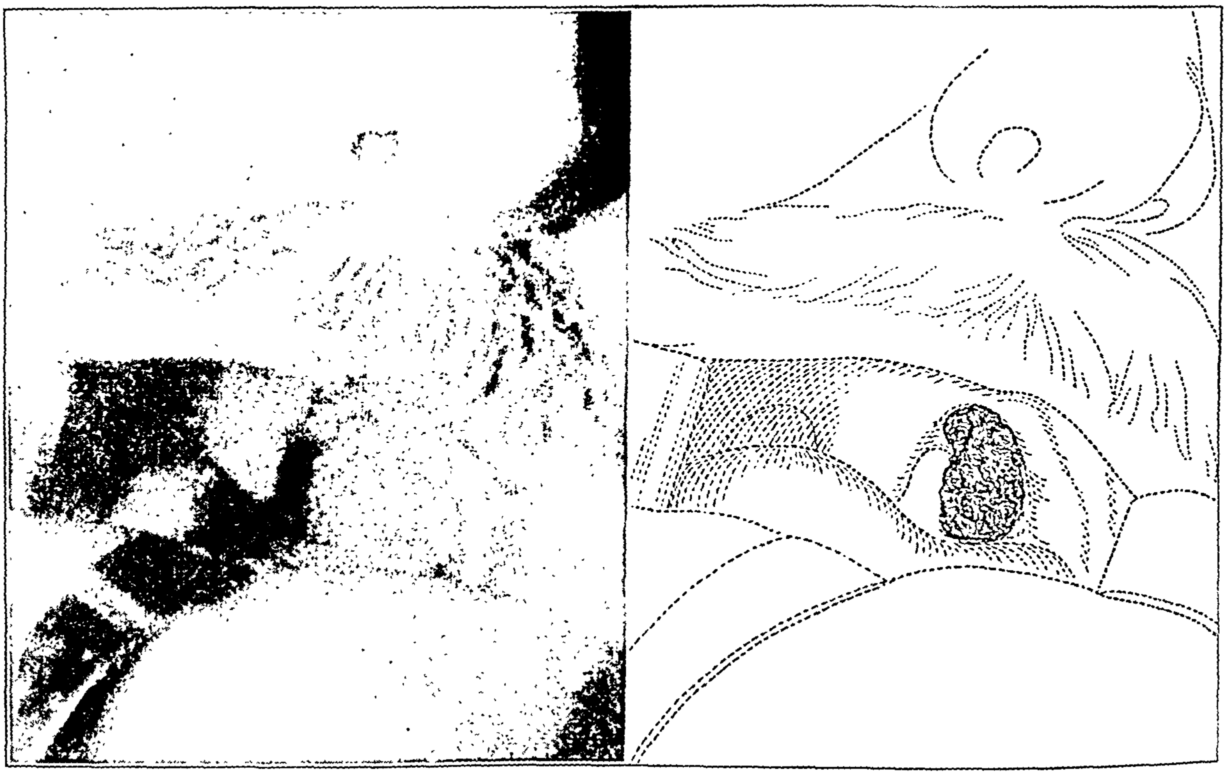

Fig. 7.—Cancer of the tonsil. The left tonsil has been partly eroded by a slowly growing ulcerated cancer.

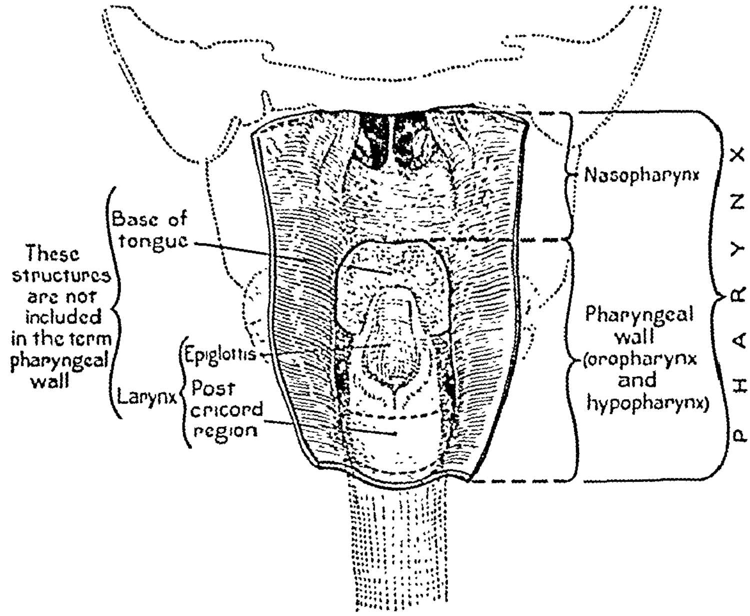
In order of their frequency the first symptoms complained of in nasopharyngeal cancer are cervical metastasis (referred to by the patient as a "lump" in the neck) and unilateral deafness or tinnitus ("stuffiness in one ear"). In about 4 out of 5 cases cervical metastases are present on admission and may be either the only symptom or associated with symptoms referable to the ear. As the disease progresses, the growth in the nasopharynx tends to erode the base of the skull in the region of the foramen lacerum, encroaching on or invading the course of the sixth cranial nerve to produce paralysis of the external rectus muscle of the eye. Consequently some patients are first seen by the ophthalmologist because of diplopia and others are referred to the neurologist. Later in the course of the disease the local tumor may invade the orbit and produce exophthalmos or extend through the eustachian tube into the middle ear to perforate the tympanic membrane.

Since growths in the nasopharynx tend to be highly anaplastic, systemic metastases are frequent and dissemination of the disease below the level of the clavicle is present in about one third of the cases on admission.

DIAGNOSIS OF NASOPHARYNGEAL CANCER

Nasopharyngeal cancer should be suspected in any one of the following situations: (1) unilateral or bilateral enlargement of cervical lymph nodes not accompanied by any localized symptoms of a primary lesion elsewhere; (2) a complaint of unilateral deafness and tinnitus either with or without enlargement of cervical lymph nodes, and (3) unilateral external rectus paralysis or diplopia. The failure to diagnose nasopharyngeal cancer early is due both to the fact that a growth in this locality is unsuspected and the fact that the nasopharynx is not easily accessible to inspection by the casual examiner (fig. 9). If a physician does not possess the necessary training and skill to examine this region, he should refer the patient to some one who is so qualified.



Nasopharynx
Base of tongue
These structures are not included in the term pharyngeal wall
Epiglottis
Larynx
Post cricord region
Pharyngeal wall (oropharynx and hypopharynx)

Fig. 8.—Anatomy of the pharyngeal wall. In an anatomic classification of cancer, it is essential that the limits of each structure be clearly defined. Cancer of the nasopharynx is an entirely different disease from cancer of the walls of the oropharynx and hypopharynx. It is important to distinguish growths of the base of the tongue and of the extrinsic part of the larynx from those of the pharyngeal wall proper.

The most effective method of examining the nasopharynx is by the use of a headlight, depressing the tongue with a wooden or metal blade and viewing the image of the nasopharynx in a throat mirror which is inserted to a point just beyond the free edge of the soft palate (topical anesthesia). During the examination the patient is asked to breathe through the mouth and the nose at the same time. By this means the entire region can be visualized. The nasopharynx cannot be so efficiently demonstrated by endoscopy (nasopharyngoscope) as by simple examination with a mirror.

TREATMENT OF NASOPHARYNGEAL CANCER

Malignant tumors of the nasopharynx are not suitable for surgical removal, both because of the relative inaccessibility of the region to the surgeon and because the growths from the beginning tend to invade the posterolateral bony walls which cannot be safely excised. On the other hand, malignant neoplasms in this region are usually highly anaplastic and, in general, radiosensitive. The nasopharynx tolerates heavy doses of radiation fairly well. For these reasons, most nasopharyngeal cancers are best treated by a combination of fractionated doses of roentgen therapy supplemented by intracavitary radium or radon.

Since cervical metastasis occurs in more than 80 per cent of all cases at some time during the course of the disease, their successful treatment is one of the most important factors in the prognosis of nasopharyngeal cancer. Because involvement of the cervical lymph nodes is so often widespread and present at the time of admission, the best results are obtained by radiation therapy rather than by neck dissection. Exceptions to such a method of treatment are made when cervical metastasis appears at an interval (six months or more) after apparent control of the primary lesion in the nasopharynx by radiation therapy; in such cases neck dissection is indicated if there is no evidence of remote metastasis.

PROGNOSIS AND END RESULTS IN NASOPHARYNGEAL CANCER

Despite the absence of localizing symptoms in many cases of early or even moderately advanced nasopharyngeal cancer and despite the frequent occurrence of diffuse and bilateral cervical metastasis, this disease is by no means a hopeless one if properly treated by aggressive radiation therapy. In contrast with growths of the mouth and larynx, the presence of cervical metastasis in nasopharyngeal cancer does not appreciably after the prognosis and can be attributed to the anaplastic and highly radiosensitive character of the lesion.

As a matter of fact, the prognosis in cancer of the nasopharynx is about the same as for that of cancer of the tongue in all stages of the disease. A five year cure rate of 20 per cent has been obtained in a relatively large series of cases (table 2).

CANCER OF THE PHARYNGEAL WALL

The term pharyngeal wall, as considered in this report, refers to the lower or broadest portion of the pharyngeal tube, that is, the posterior and lateral walls, and does not include the base of the tongue and the extrinsic larynx (fig. 8). This portion of the pharynx consists of smooth walls with no functionally important structures, so that cancer in this locality produces no dysfunction until the growth is relatively well advanced or has invaded a contiguous area such as the palatine tonsil, the base of the tongue or the extrinsic larynx.

Table 2.—*Five Year Cure Rates in Cancer of the Pharynx and Larynx* *

Anatomic Site	Number of Cases	Percentage of Five-Year Cures
Nasopharynx	87	20
Pharyngeal wall	108	5
Larynx	351	
Intrinsic	164	31
Extrinsic	187	10

* Head and Neck Service, Memorial Hospital.

ETIOLOGY OF CANCER OF THE PHARYNGEAL WALL

Cancer of the pharyngeal wall, as defined, is relatively uncommon in the United States, comprising about 0.5 per cent of all human cancer and about 3 per cent of all cancer in the upper respiratory and alimentary tracts. In America this disease occurs more frequently in males (85 per cent of the cases), but in Scandinavian countries the disease is more commonly encountered in females (over 60 per cent). This susceptibility of females in Scandinavian countries can be attributed to the frequent occurrence of Plummer-Vinson's disease, in which, among other manifestations, there is a chronic inflammation of the hypopharynx. This inflammation constitutes the irritative factor so often found as a contributing cause in malignant growths of surface epithelium.

PATHOLOGY OF CANCER OF THE PHARYNGEAL WALL

As in other anatomic varieties of cancer in the upper respiratory and alimentary tracts, epidermoid or squamous carcinoma is the predominant morphologic type found in the pharyngeal wall (90 per cent). About one half of the malignant tumors in this region are poorly differentiated cancers (grade 3), and such a degree of anaplasia is most frequently encountered the nearer the location of the growth to the extrinsic larynx. Cancer in the lowermost portion of the pharyngeal wall (hypopharynx), therefore, is more highly malignant and in this way simulates growths of the peripheral portions of the extrinsic larynx. Other morphologic types of cancer which are encountered but rarely in the pharyngeal wall are spindle cell sarcoma and adenocarcinoma originating in a minor salivary gland.

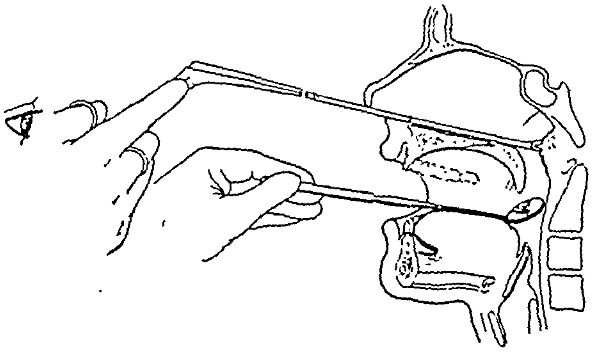


Fig. 9.—Biopsy from nasopharynx guided by mirror. One of the simplest methods of obtaining a biopsy from the nasopharynx is by inserting an instrument through the nasal cavity and guiding its manipulations by a mirror inserted through the mouth.

SYMPTOMS, MORBID ANATOMY AND CLINICAL COURSE OF CANCER OF THE PHARYNGEAL WALL

From the standpoint of early symptoms cancer of the pharyngeal wall is one of the more deceptive neoplasms occurring in the head and neck. Since the smooth walls of the pharynx contain no functionally important structures, the growth in all cases reaches a fairly large size before the patient becomes aware subjectively of any abnormality.

The chief early symptom complained of by the patient with this disease is some form of discomfort in the throat, such as slight pain on swallowing or a feeling of irritation in the throat. At times the complaint referred to in this region may be so vague and indefinite that the history resembles that of globus hystericus or anxiety neurosis. In the later stages, there may be frank dysphagia. Lesions which arise primarily in the piriform sinus or close to the peripheral portions of the extrinsic larynx give rise to dysphagia earlier in the course of the disease than growths which originate at higher levels on the posterior or lateral pharyngeal walls.

The second most frequent symptom is the appearance of cervical metastasis (usually referred to by the patient as a "lump" in the neck). At the time of the first examination such metastases are found in over 60 per cent of the patients. Occasionally, cervical metastasis occurs as the first symptom with no complaints referable to the throat (silent primary).

As the disease progresses, the dysphagia increases, and there may be considerable loss of weight, and with extension of the growth to the structures of the larynx hoarseness occurs. In the terminal stages, the tonsil may be invaded, resulting in intractable pain referred to the ear, or the tumor may extend forward and upward along the lateral walls into the base of the tongue. If the cancer is not controlled, death may occur either from extensive metastasis or local sepsis and malnutrition.

On physical examination the primary lesion presents as a bulky mass arising in the lateral or posterior wall (or both), or as a *flat, indurated, granular ulcer.* In most cases the growth, when first seen, will have reached the size of at least 2 to 3 cm., with ulceration and infection in both the tumor and the surrounding tissues. The lateral wall of the pharynx is the site of cancer more than twice as often as the posterior wall, and when the posterolateral wall is involved the tumor is usually far advanced.

DIAGNOSIS OF CANCER OF THE PHARYNGEAL WALL

In the diagnosis of cancer of the pharyngeal wall there are two important points for the physician to keep in mind. The first is that chronic sore throat or dysphagia indicates the possibility of a growth in this region, and the second that the presence of enlarged cervical lymph nodes in the absence of any other symptom suggests metastasis from a silent primary lesion somewhere in the oral cavity or pharynx.

From the standpoint of accurate diagnosis and as a requisite to properly planned treatment, it is essential to distinguish tumors of the pharyngeal wall from those of other structures adjacent to the pharynx, such as the extrinsic larynx (postcricoid region), the base of tongue and the tonsil. Growths in the latter regions are distinct clinical entities and often call for methods of treatment differing from those given for malignant neoplasms of the pharyngeal wall itself.

It is always difficult to distinguish between a growth arising in the postcricoid portion of the extrinsic larynx and one in the posterior pharyngeal wall at this same level, since by indirect laryngoscopy all that can be seen is a granular mass protruding slightly from the postarytenoid region. A proper plan of treatment can be outlined only after the findings have been evaluated by endoscopy and the anatomic differentiation definitely established.

Biopsy.—The clinical diagnosis of cancer of the pharyngeal wall, which can be made without difficulty in most cases, should be promptly confirmed histologically by biopsy. Removal of a specimen of tissue from this area can be performed either with a straight biopsy forceps under direct vision (oropharynx) or by use of a curved biopsy forceps and a throat mirror if the lesion is located in the lower portion of the pharyngeal tube (hypopharynx).

TREATMENT OF CANCER OF THE PHARYNGEAL WALL

Until recently the posterior and lateral walls of the pharynx have not been considered readily accessible from the surgical standpoint. For growths of the piriform sinus, surgical excision hitherto has appeared to be contraindicated because of the necessity of an associated total laryngectomy and the difficulty in the subsequent reestablishment of a satisfactory channel from the pharynx into the esophagus. Moreover, since malignant tumors in such continguous areas as the palatine tonsil and the base of the tongue have responded reasonably well to radiation therapy, it was formerly thought that a similar result might be logically expected in the adjacent pharyngeal wall. For these reasons, therefore, cancer of the pharyngeal wall has been treated previously almost exclusively by radiation therapy.

More recently the attitude toward cancer of the pharyngeal wall has undergone some modification. In the first place, a survey of all cases (both early and advanced) in one cancer clinic has revealed that the net cure rate by radiation therapy is only about 5 per cent—hardly a satisfactory salvage in any disease. On the other hand, modern surgical aids such as chemotherapy, antibiotics, blood transfusion, new technics of anesthesia along with improved preoperative and postoperative care have made it possible to extend the range of surgery to include the region of the pharynx. It has been found possible, therefore, to approach growths of the lateral and posterior pharyngeal walls by pharyngotomy. Many lesions situated in this area may be widely excised and the wound primarily closed. For growths of the piriform sinus and the posterior pharyngeal wall just above the cricopharyngeus a choice must be made between the discouragingly low rate of cure by radiation therapy on one hand and the disability and morbidity following total laryngectomy and partial pharyngectomy with reconstruction of the esophagus on the other. Despite these surgical advances, however, the majority of cases will be found too advanced for excision. For the latter, fractionated radiation therapy, sometimes supplemented by interstitial radium or radon for cervical metastasis, is the only treatment available at present and in a small percentage will result in a permanent cure.

PROGNOSIS AND END RESULTS IN CANCER OF THE PHARYNGEAL WALL

The local lesion in the pharyngeal wall, especially when situated near the piriform sinus, tends to be less radiosensitive than similar growths in the extrinsic larynx. In some cases, although the visible portions of the tumor in the pharynx may apparently respond favorably to radiation, the symptoms recur nevertheless after a period of twelve to eighteen months and investigation will reveal that the neoplasm has extended into the upper portion of the esophagus. In addition, the complication of radionecrosis in this locality is serious since it tends to be accompanied by mediastinitis and pronounced dysphagia.

The presence of cervical metastasis in the beginning or at any stage during the course of the disease lowers the chances of cure. In a large series of cases in one head and neck clinic the five year cure rate following radiation therapy for cancer of the pharyngeal wall is about 5 per cent when all patients (in all stages of the disease) are included (table 2). It is too early to ascertain whether the use of radical surgery (pharyngotomy and partial pharyngectomy with total laryngectomy) in operable cases will improve this rate of cure, but the short term results following such a method of treatment suggest further efforts in this direction.

SUBACUTE BACTERIAL ENDOCARDITIS DUE TO HEMOPHILUS PARAINFLUENZAE

Report of a Case with Recovery Following the Combined Use of Penicillin and Sulfamerazine

CHAS. J. McGEE, M.D.
and
WALTER S. PRIEST, M.D.
with the technical assistance of
DOLORES KENNEY, M.T.
Chicago

This case is presented because of its unusual etiologic organism and successful outcome and to emphasize the possibility of almost complete recovery from the effects of cerebral embolism occurring during the course of bacterial endocarditis. Hemophilus parainfluenzae is a member of a group of organisms classified as follows: [1]

Class A:	Require X factor and V factor:	Hemophilus influenzae
B.	Require V factor:	Hemophilus parainfluenzae
C:	Require X factor:	Hemophilus hemoglobinophilus canis
D:	Require neither:	Hemophilus pertussis

Of these, H. influenzae and H. parainfluenzae are known to cause endocarditis.[2] H. parainfluenzae has also been known to cause leukopenia, cutaneous rash [3] and bacteremia.[4] Khairat [5] reported endocarditis caused by a Hemophilus the cultural and morphologic characters of which were different from those of H. parainfluenzae. An atypical H. influenzae is reported as the etiologic organism in infection of a patent ductus arteriosus.[6] In 1938, Miles and Gray [2b] collected 34 cases of subacute bacterial endocarditis caused by Hemophilus organisms. Seven of these were proved to be H. parainfluenzae, and the authors expressed the opinion that most of the others were probably H. parainfluenzae, though not proved by growth requirements for X and V factors. Bloom [2c] reported 1 case; Craven, Poston and Orgain [1] 2 cases of endocarditis due to H. parainfluenzae, confirmed by autopsy; Rose [2d] 1 case of H. influenzae type A endocarditis.

H. parainfluenzae is a small pleomorphic, nonmotile, nonsporing, Gram-negative, non-acid-fast coccobacillus. It has no capsule. It is hemophilic but nonhemolytic. It can synthesize X factor but not V factor. Certain strains produce acid but not gas in certain of the saccharides, but not all observers have been in agreement as to which. H. influenzae never produces acid in lactose and mannitol.[7] Litmus milk is unchanged by H. parainfluenzae; indole and hydrogen sulfide are not produced [7]; nitrates are reduced. Mild satellism (limited production of V factor) is shown with Staphylococcus aureus. It is not pathogenic for mice, rabbits or guinea pigs.

There has been some controversy as to the nature of the growth requirements (X and V factors) and what may be used for substitutes. Zinsser [8] pointed out that X and V factors must be present in blood and expressed the doubt that V factor is vitamin C. Lwoff and Lwoff [9] maintained that

in males (85 per cent of the cases), but in Scandinavian countries the disease is more commonly encountered in females (over 60 per cent). This susceptibility of females in Scandinavian countries can be attributed to the frequent occurrence of Plummer-Vinson's disease, in which, among other manifestations, there is a chronic inflammation of the hypopharynx. This inflammation constitutes the irritative factor so often found as a contributing cause in malignant growths of surface epithelium.

PATHOLOGY OF CANCER OF THE PHARYNGEAL WALL

As in other anatomic varieties of cancer in the upper respiratory and alimentary tracts, epidermoid or squamous carcinoma is the predominant morphologic type found in the pharyngeal wall (90 per cent). About one half of the malignant tumors in this region are poorly differentiated cancers (grade 3), and such a degree of anaplasia is most frequently encountered the nearer the location of the growth to the extrinsic larynx. Cancer in the lowermost portion of the pharyngeal wall (hypopharynx), therefore, is more highly malignant and in this way simulates growths of the peripheral portions of the extrinsic larynx. Other morphologic types of cancer which are encountered but rarely in the pharyngeal wall are spindle cell sarcoma and adenocarcinoma originating in a minor salivary gland.

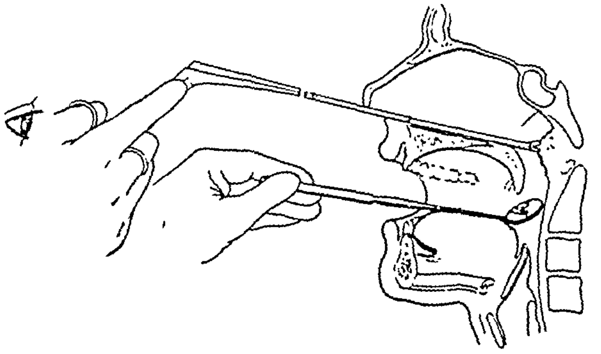

Fig. 9.—Biopsy from nasopharynx guided by mirror. One of the simplest methods of obtaining a biopsy from the nasopharynx is by inserting an instrument through the nasal cavity and guiding its manipulations by a mirror inserted through the mouth.

SYMPTOMS, MORBID ANATOMY AND CLINICAL COURSE OF CANCER OF THE PHARYNGEAL WALL

From the standpoint of early symptoms cancer of the pharyngeal wall is one of the more deceptive neoplasms occurring in the head and neck. Since the smooth walls of the pharynx contain no functionally important structures, the growth in all cases reaches a fairly large size before the patient becomes aware subjectively of any abnormality.

The chief early symptom complained of by the patient with this disease is some form of discomfort in the throat, such as slight pain on swallowing or a feeling of irritation in the throat. At times the complaint referred to in this region may be so vague and indefinite that the history resembles that of globus hystericus or anxiety neurosis. In the later stages, there may be frank dysphagia. Lesions which arise primarily in the piriform sinus or close to the peripheral portions of the extrinsic larynx give rise to dysphagia earlier in the course of the disease than growths which originate at higher levels on the posterior or lateral pharyngeal walls.

The second most frequent symptom is the appearance of cervical metastasis (usually referred to by the patient as a "lump" in the neck). At the time of the first examination such metastases are found in over 60 per cent of the patients. Occasionally, cervical metastasis occurs as the first symptom with no complaints referable to the throat (silent primary).

As the disease progresses, the dysphagia increases, and there may be considerable loss of weight, and with extension of the growth to the structures of the larynx hoarseness occurs. In the terminal stages, the tonsil may be invaded, resulting in intractable pain referred to the ear, or the tumor may extend forward and upward along the lateral walls into the base of the tongue. If the cancer is not controlled, death may occur either from extensive metastasis or local sepsis and malnutrition.

On physical examination the primary lesion presents as a bulky mass arising in the lateral or posterior wall (or both), or as a flat, indurated, granular ulcer. In most cases the growth, when first seen, will have reached the size of at least 2 to 3 cm., with ulceration and infection in both the tumor and the surrounding tissues. The lateral wall of the pharynx is the site of cancer more than twice as often as the posterior wall, and when the posterolateral wall is involved the tumor is usually far advanced.

DIAGNOSIS OF CANCER OF THE PHARYNGEAL WALL

In the diagnosis of cancer of the pharyngeal wall there are two important points for the physician to keep in mind. The first is that chronic sore throat or dysphagia indicates the possibility of a growth in this region, and the second that the presence of enlarged cervical lymph nodes in the absence of any other symptom suggests metastasis from a silent primary lesion somewhere in the oral cavity or pharynx.

From the standpoint of accurate diagnosis and as a requisite to properly planned treatment, it is essential to distinguish tumors of the pharyngeal wall from those of other structures adjacent to the pharynx, such as the extrinsic larynx (postcricoid region), the base of tongue and the tonsil. Growths in the latter regions are distinct clinical entities and often call for methods of treatment differing from those given for malignant neoplasms of the pharyngeal wall itself.

It is always difficult to distinguish between a growth arising in the postcricoid portion of the extrinsic larynx and one in the posterior pharyngeal wall at this same level, since by indirect laryngoscopy all that can be seen is a granular mass protruding slightly from the postarytenoid region. A proper plan of treatment can be outlined only after the findings have been evaluated by endoscopy and the anatomic differentiation definitely established.

Biopsy.—The clinical diagnosis of cancer of the pharyngeal wall, which can be made without difficulty in most cases, should be promptly confirmed histologically by biopsy. Removal of a specimen of tissue from this area can be performed either with a straight biopsy forceps under direct vision (oropharynx) or by use of a curved biopsy forceps and a throat mirror if the lesion is located in the lower portion of the pharyngeal tube (hypopharynx).

TREATMENT OF CANCER OF THE PHARYNGEAL WALL

Until recently the posterior and lateral walls of the pharynx have not been considered readily accessible from the surgical standpoint. For growths of the pirientered Wesley Memorial Hospital acutely and chronically ill, and showed many manifestations of his disease before recovery was accomplished. In attempting to explain why the combination of penicillin and sulfamerazine effected a cure when sulfamerazine alone did not, it appears most logical to assume that penicillin, which has now been proved to penetrate fibrin,[13] in some manner was able to carry sulfamerazine to the bacteria beneath the fibrin of the valvar vegetations or to alter the diffusion characteristics of the fibrin toward sulfonamide compounds. Since H. influenzae and parainfluenzae organisms are sensitive to streptomycin, this would be the choice of therapeutic agents today.

Undoubtedly this boy had an embolus to the brain the consequences of which appeared rather serious at the time of its occurrence. However, two years later there is practically no sequela therefrom. It behooves us, especially in view of similar experiences which we have had,[14] to realize that in subacute bacterial endocarditis such complications are not necessarily of gloomy significance.

SUMMARY

A case of recovery from subacute bacterial endocarditis due to Hemophilus parainfluenzae is presented. So far as we could find this is the first such recovery to be reported.

The literature was reviewed; 39 previous cases of subacute bacterial (Hemophilus) endocarditis and 1 case of an infected patent ductus arteriosus due to atypical H. influenzae were found. All these terminated fatally.

The bacteriology of H. parainfluenzae is reviewed.

Cerebrovascular accidents occurring during the course of subacute bacterial endocarditis do not necessarily produce significant permanent sequelae.

The ability of penicillin to render fibrin permeable to sulfonamide drugs or to carry sulfonamide drugs past a fibrin barrier is demonstrated clinically.

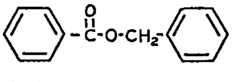
Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for Admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

Austin Smith, M.D., *Secretary.*

BENZYL BENZOATE, U.S.P.—$C_{14}H_{12}O_2$—A clear, colorless oily liquid with slight aromatic odor employed externally in various emulsions containing 25 to 30 per cent. The structural formula of benzyl benzoate may be represented as follows:



For standards, see U.S. Pharmacopeia under Benzyl Benzoate and Benzyl Benzoate Lotion.

Actions and Uses.—Benzyl benzoate applied externally in the form of a 25 to 30 per cent emulsion or lotion has been found to be an effective scabicide. Although, reported to be somewhat effective also as a pediculicide, its use for pediculosis uncomplicated by scabies is not recommended. Application is occasionally followed by a slight, transitory burning sensation. Rarely, severe skin irritation may occur in patients with particularly sensitive skins. It should never be allowed to come in contact with the eyes.

Dosage.—A 25 to 30 per cent lotion or emulsion of benzyl benzoate is applied with a swab or brush over the entire body surface (*except the face*) while the skin is still damp immediately following scrubbing of the lesions in a 10 minute soap-warm water bath. Care should be taken to insure application to and around the nails. The first application is allowed to dry and a second application made to the most involved areas. Children ordinarily require 60 cc. to 90 cc. and adults 120 cc. to 180 cc. for a single treatment. Adequate sterilization of bed and body clothing is essential. Twenty-four hours later, clean clothing is put on after a warm soaking bath. A second or third treatment following the same routine should be carried out if necessary to eradicate the parasite. Secondary pyogenic infections do not contraindicate treatment, but should receive appropriate measures.

George A. Breon and Company, Kansas City, Mo.

Lotion Benylate: 120 cc., 480 cc. and 3,840 cc. bottles. An oil in water emulsion containing 25 per cent of benzyl benzoate and approximately 2 per cent of triethanolamine stearate. The product is required to be labeled as Modified Benzyl Benzoate Lotion because it differs from the official benzyl benzoate lotion, U.S.P. essentially by the emulsifying agent used in its preparation.

CARBOL-FUCHSIN PAINT. — Carfusin-Rorer. — A solution containing boric acid 1%, phenol 4.5%, resorcinol 10%, fuchsin 0.3%, acetone 5% in water, q.s.

The boric acid, phenol, resorcinol, fuchsin and acetone used in the preparation of this particular preparation meet the requirements of the U. S. Pharmacopeia or The National Formulary.

Actions and Uses.—Carbol-Fuchsin paint is a stabilized preparation of the original basic fuchsin formula known as Castellani's paint that is widely employed for topical application to superficial fungus infections of the skin. Its use should be restricted to subacute or chronic dermatophytoses; it has been found to be of value for epidermophytosis interdigitalis pedum ("athlete's foot"), other intertriginous lesions of fungus origin, tinea trichophytina (ringworm) and tinea imbricata.

Carbol-fuchsin paint has the advantage over the original and subsequently modified preparations in that it is stable, but it should be protected against evaporation. It shares with other triphenylmethane dyes the disadvantage that it will stain clothing with which it comes in contact. It should never be applied to large areas of the body or to patients with particularly sensitive skins. A test application of a 1 : 3 dilution should be made to a single small lesion before beginning treatment with the full strength paint. It should be properly guarded against accidental ingestion because of the poisonous character of the ingredients.

Dosage.—Carbol-fuchsin paint is applied full strength directly to the surface of the skin lesions. Thorough topical application once or twice daily is indicated in subacute phases; three times daily in chronic or particularly stubborn lesions. Interim use of a foot powder and twice daily change of hosiery is recommended in the treatment of epidermophytosis pedis. In cases associated with excessive drying of the skin, application of the paint may be continued in conjunction with applications of either boric acid ointment containing 2 to 5 per cent of ammoniated mercury or an ointment of petrolatum containing 1 per cent each of sulfur and salicylic acid and 25 per cent each of zinc oxide and talc.

William H. Rorer, Inc., Philadelphia

Carfusin: 30 cc. and 120 cc. bottles. A solution of boric acid 1%, phenol 4.5%, resorcinol 10%, fuchsin 0.3%, acetone 5% in water, q.s.

U. S. trademark applied for.

RABIES VACCINE (ULTRAVIOLET IRRADIATION KILLED).—Brains of rabbits paralyzed by infection with fixed rabies virus are harvested, emulsified and brought to a 10 per cent by weight suspension of tissue in isotonic solution of sodium chloride and filtered through sterile bolting silk. Following filtration, the tissue suspension in a continuously flowing thin film is exposed to the germicidal rays of ultraviolet lamp. Preserved with sodium ethyl mercuri thiosalicylate 1 : 10,000.

Actions and Uses.—Rabies Vaccine (Ultraviolet Irradiation Killed) is employed for the prophylaxis of rabies.

Dosage.—1 cc. subcutaneously, daily for 14 to 21 days. For severe exposure-bites on face or adjacent to central nervous system, 21 doses, two daily for the first three to seven days and then one dose daily.

Pitman-Moore Company, Indianapolis

Rabies Vaccine (Ultraviolet Irradiation Killed): 1 cc. vials packaged in units of seven vials. Preserved with sodium ethyl mercuri thiosalicylate 1 : 10,000.

EDITORIAL ANNOUNCEMENT

The compositors returned to work on Monday, June 28. This issue of The Journal has been prepared in part by the use of Vari-Typer machines.

MEDICAL SERVICE WITH THE ARMED FORCES

Now that the disorder associated with demobilization of the armed forces following World War II has begun to recede into history, physicians concerned with the services of medical men in time of war have begun to give serious attention to the supply of doctors for the Army under the new Selective Service Act and also in times of crisis or war. Right now the surgeons general of the Army and the Navy and the Air Surgeon are in constant communication over the critical situation that confronts these services in securing enough physicians to take care of men who will be called into duty under the Selective Service Act. At the same time, the Council on National Emergency Medical Service, under Dr. James C. Sargent, chairman, is giving careful consideration to the relationship of the American Medical Association to military needs; representatives of the Association are conferring with other governmental agencies—the public health services, the Veterans Administration and all of the other federal activities that have a need for doctors—regarding the supply of physicians for civilian defense.

Many men who served during World War II are bitter in their recriminations as to faults which they observed in utilization of the medical profession. Some of these faults were so obvious that military leaders have already taken steps to bring about correction. One of the main objections related to the employment of doctors and dentists in work that was administrative rather than professional. The Office of the Surgeon General of the Army now gives assurance that every doctor and dentist has been removed from every administrative position that does not require a professionally trained man. The Inspector General's department has made a worldwide survey of professionally trained men in the armed forces and has aided in this action. The study continues; medical service corps officers will be used wherever possible to replace physicians and dentists in nonprofessional positions.

Another objection, particularly from the young men associated with the armed forces, was the lack of continuous graduate training and the opportunity to advance in a medical specialty while rendering service in the Army. The Army Medical Department has recognized the inestimable value to that department of civilian professional consultants. These are now used not only in the graduate education program but also in maintaining the highest medical standards in the care of military personnel. Every effort is being made to extend the usefulness of these consultants during the present crisis. However, a new difficulty arises in relationship to the Selective Service Act, because training camps for selectees will be placed in areas removed from centers of population. Because of the difficulty of reaching these training centers, few civilian consultants are in a position to provide twenty-four hour coverage as consultants to Army hospitals.

During World War II, one of the most serious complaints related to wastage of physicians by maintaining in close contact installations of the Army, the Navy and the Air Forces with complete staffs of specialists who, in many instances, did not have enough actual work to occupy their time. Now a detailed study has been, and is continuing to be, made to determine where it is possible to combine certain medical activities and to eliminate others and thus to abolish waste of professional personnel. The committee headed by General Hawley has completed its study of the situation in Panama, and combinations are to be made there which will bring about a vast saving in medical personnel. No doubt similar action will be taken in other areas in which multiple installations might be combined.

The suggestion has frequently been made that civilian physicians be employed on a part or full time basis by the armed forces and remunerated as contract physicians for the aid that they can give as physicians in the care of military personnel. Unfortunately the remuneration offered to civilian physicians to render services to military installations compares so unfavorably with that obtainable from private practice that few physicians volunteer for this service. The Army is not optimistic about this source of professional help. However, physicians who wish to participate and to whom the income is not the significant factor might well communicate with the Surgeon General, U. S. Army or Navy, Washington, D. C., as to the possibility of offering their services.

The Army, Navy and Air Force are cooperating in an endeavor to economize in personnel by using air evacuation as a replacement for ship evacuation of the wounded. If hospital ships, with their attending medical personnel, can be eliminated in whole or in part, a saving may be obtained. Among other possibilities the utilization of hospitals of other federal agencies, the shortening of the stay of patients in hospitals so as to expedite their return to duty, the elimination of dependent care and the curtailment of the graduate education program are being considered. Any of these actions might seriously affect the morale of the men who serve and might also bring about a deterioration in the attitude of physicians and other medical personnel toward military service.

The procurement programs of the Army and Navy have fallen far short of producing the required professional personnel. Unless the Congress provides additional incentives to make such services appeal more definitely to physicians, medical technicians, nurses and other medical personnel, a real crisis will develop. The committees which have been considering these problems believe that thought must be given to increase in remuneration, since the pay of physicians and other personnel in the armed forces is not comparable to that in civilian life. While some security is provided for medical officers, government agencies do not offer security for the families of military personnel. Most serious, however, has been the complaint as to the provision of adequate and respectable housing. Medical officers dislike particularly the separation from their families for many months, which seems to be an unfavorable accompaniment of service with the armed forces. Men are constantly moved, and apparently far too frequently, from place to place. The schooling of children is interrupted. Unless a medical officer is a professional expert in the field of real estate, he may incur a considerable monetary loss in buying, selling and leasing residences as he changes from one assignment to another. Over these difficulties the Surgeon General has little, if any, control. The Surgeon General can of course encourage the development of high professional standards, give opportunity for attendance of military personnel at professional meetings, improve working conditions in the hospital and develop a more efficient method of support and guidance from senior medical officers among those in the lower ranks.

The situation today in all of the armed forces is, as has here been emphasized again and again, exceedingly critical. The exact number of physicians needed during the coming year may well approach 6,000, of whom the majority would be for the Army and Air Force and the rest for the Navy. The supply of professional personnel now apparent is deficient. Unless the rate of procurement of officers is rapidly—and substantially—increased and maintained, the ability to provide medical care under the Selective Service Act is jeopardized. The Congress did not include in the Selective Service Act a specific draft of doctors; but President Truman has recalled the Congress and conceivably may again insist on such a draft if the needs of the armed forces are not met by voluntary offers of service from the medical profession.

Most of the young men who have given military service are not inclined to volunteer. There are, however, thousands of young men who were educated at government expense in the ASTP and the V-12 programs and who did not render actual military service. They owe an obligation to the government and to the people of the United States. They are representatives of the medical profession to whom the people look for the proper care of our armed forces.

In their procurement programs for regular officers, the medical departments of the armed forces, by cooperation with the specialty training boards, are able to provide assistant residencies and residencies in both military and civilian installations, which will be accredited by the certifying boards following satisfactory completion of the service. These positions should appeal particularly to the young men who have graduated in recent years, since they offer opportunity for training in a specialty with an adequate income, housing and maintenance not available through any other source.

The Council on National Emergency Medical Service, the Board of Trustees of the American Medical Association and all its officials are doing their utmost to aid the armed forces in this crisis. Every physician should give thought to the extent to which he individually can help in this time of need.

Current Comment

NINTH INTERNATIONAL CONGRESS ON INDUSTRIAL MEDICINE

After a lapse of ten years, the International Congresses on Industrial Medicine are being resumed. The ninth of this series will take place in Caxton Hall, Westminster, London, Sept. 13 to 17, 1948. The sponsoring agency is the Commission Internationale Permanente pour la Médecine du Travail, having headquarters at Geneva. The imposing list of patrons includes the King and Queen, Cabinet heads, and the presidents of the Royal Colleges. Six section programs are listed in the preliminary announcement, including social aspects, environmental industrial medicine, industrial nursing, clinical problems, administrative practices, and a special section which deals with legislation, education and technical problems not classified under other main headings. Each section has a chairman and secretary, most of whom are well known in this country as representing industrial medical leadership in England. There are to be ancillary exhibitions and clinics in hospitals, rehabilitation centers and industrial medical departments both in and out of London. This Congress will be the outstanding industrial medical event of the year. Those interested in attending may obtain further information from the organization secretary, in care of the British Medical Association House, Tavistock Square, London, W.C.1.

CANCER OF THE URINARY BLADDER

Shifts in the relative incidence rate of cancers of certain organs during recent years have been attributed to improvements in diagnostic methods, to more complete statistical analyses of necropsy material and death certificates and to definite advancements in the treatment of tumors in accessible organs. The control of accessible cancer may cause a relative increase in the mortality from cancers of inaccessible organs. The enormous growth of modern industry during recent years may have brought about alterations in the exogenous part of the carcinogenic spectrum. The discovery of an ever increasing number and variety of occupational, medicinal and environmental cancers during the last fifty years supports this concept. Changes in the composition of external carcinogenic environment may have contributed to fluctuations in the rates of cancer of various organs. In addition to cancer of the lung and leukemia, cancer of the urinary bladder displayed a significant increase since the early part of this century. As 3 per cent of the cancer deaths are caused by cancer of the bladder, approximately 90,000 persons have died from this tumor in the United States during the last twenty years. Seventy thousand of these were males. The mortality rate from cancer of the bladder some fifty years ago was 1.3 to 1.5 per cent of the total death rate from cancer. In about 200 of the 70,000 cases of cancer of the urinary bladder in males an occupational exposure to 2-naphthylamine or benzidine was established (0.3 per cent) as the causative factor. However, the actual number of cases of cancer of the bladder of this origin is doubtlessly higher. Physicians, as a rule, do not ascertain the entire occupational history of their cancer patients and thereby miss the pertinent data on carcinogenic occupational exposures which may have taken place some five to twenty years before the cancers became manifest. Observations by Kennaway and Kennaway in England suggest, moreover, that occupational contact not only with aromatic amines but possibly also with tar, pitch and mineral oil seems to produce an increased liability not only to cancer of the skin but also to cancer of the bladder. Experimental results indicate further that several aromatic compounds, such as amino-2,3'-azotoluene, ortho-toluidine, and 2-acetylaminofluorene, produce cancer of the bladder in animals on a deficient diet. Recent observations in experimental animals and man support the point of view that carcinogenic substances excreted in the urine are responsible for the development of certain cancers in the bladder. Strombeck[1] showed in rats fed 2,3'-azotoluene that papillomatous tumors do not arise in a piece of bladder mucosa explanted in the liver, while they develop in the bladder stump. Steele Koch and Steiner[2] reported the presence of a carcinogenic factor in the butyl alcohol extract of human urine, and Ekman and Strömbeck[3] isolated from the urine of rats, fed azotoluene, meta-toluidine and ortho-toluidine, which they showed to be blastogenic to the vesical mucosa of rats. These investigators obtained from the urine of patients with nonoccupational cancer of the bladder not inconsiderable amounts of primary aromatic amines, some of which might even be present in oxidized form. These observations are of definite significance to warrant extensive investigations about these lines and to stimulate a detailed analysis of the occupational and environmental background of all patients with cancer.

TIME DISTORTION IN HYPNOSIS

Time perception is subject to wide variation. Events occupying days and months may in a dream be compressed into a few minutes. A person facing a terrifying experience such as an execution may see his entire life pass before his mental eye as in a flash. Cooper[1] reports interesting experiments on deliberately distorting time sense in a hypnotized person. A person placed in a hypnotic trance was asked to count cows for a suggested thirty minute period. The signal to stop counting was given three seconds later. The number of cows counted was 137. In similar experiments the hypnotized person counted 112 soldiers in three seconds, and 862 cotton bolls in three seconds. In another test the hypnotized person was told that a band was playing and that she was to listen to it. She was interrupted after thirty seconds and reported that she had been listening for nine minutes. Cooper states that there is no explanation for the state of mind which enables one while in the hypnotic trance to perform the amazing stunt of counting 862 cotton bolls in three seconds. The experiments raise the question of whether or not persons in a hypnotic trance may not make judgments

in a mere fraction of the time ordinarily required.

ATRIAL APPENDECTOMY

Formation of a thrombus in the left atrial appendage and subsequent embolism are frequent sequelae of rheumatic mitral stenosis. Surgical excision of the thrombus-containing appendage suggests itself as a possible therapeutic measure. As a preliminary step to such an operation, tests were made by Hellerstein and his associates of the Cardiovascular Department, Michael Reese Hospital, Chicago, on the effects of amputation of one or both atrial appendages in dogs. The heart was exposed through an incision in the left fifth or sixth intercostal space, and the atrial appendage isolated by special clamps. The base of each appendage was ligated proximal to the clamp and finally amputated. Thus far, eight animals have been used, 5 undergoing left, 2 right and 1 bilateral atrial appendectomy. The first animal experienced respiratory difficulty and died fifteen minutes after closure of the chest. The remaining 7 animals made uneventful recoveries. Serial electrocardiograms before and after the operation failed to reveal any abnormal atrial rhythm or evidence of atrial injury except in 1 dog in which transient intra-atrial block developed. In all cases, necropsy performed four to twelve weeks after the operation revealed complete endothelialization at the site of the atrial scar. Subjacent mural thrombi were not found. Pericardial and pleurocardial adhesions occurred in most cases. The conclusion was drawn that excision of one or both atrial appendages is a feasible operation in dogs.

IDENTIFICATION OF DISEASE IN MEDICAL PROGRESS

In an address at the hundredth meeting of the Medical Society of Virginia Shryock,[1] medical historian, discussed modern medical progress. More advance, he emphasized, has been made in preventing and curing disease in the last fifty to one hundred years than in all previous time. The medical treatment of the previous century with its bleeding and purging was not only futile but dangerous. In less than a century the average life expectancy doubled. How did this marvelous progress come about? The usual answer has credited the discoveries about 1880 of the bacterial causes of many infectious diseases. Shryock, in his answer, places more emphasis on the identification of diseases by pathologists and clinicians from 1800 to 1850. He traces the growth of the concept of the specificness, the individuality, in disease from the early recognition of symptomatic patterns and the correlation of symptoms with definite structural changes by Morgagni in 1758 to the descriptions of definite diseases by Louis, Laennec, Bright, Rokitansky, Gerhard and others in the first half of the last century. One should not overlook the significance of the discoveries even earlier of vaccination against smallpox, the cure of malaria by cinchona bark, and the value mercury in syphilis before the causes of these diseases were understood. The concept of specificness of disease was strengtnened by the responses of these diseases to special methods. Identification of diseases led to specific prevention and treatment and in surgerv to new fields and technics as antisepsis and asepsis were introduced. Before recognition of definite diseases physicians were trying to control diseases which were not understood. Anthrax tuberculosis, pneumonia, typhoid and other infections could not be worked out fully as entities "until their individuality had been discovered and defined." "Pathology led to the search for causes." Pasteur and Koch reaped where clinicians and pathologists had sown. But the conditions under which they worked do not in any way lessen the importance of their achievements. Shryock has advanced the explanation of modern medical progress by calling attention to the underlying importance in this progress of the understanding of specificness of disease. At the same time medical philosophers should not overlook the great gains made by medicine through discoveries in the basic sciences which were utilized in medicine and the benefits of adaptation to medicine of technologic discoveries such as magnification, electric light, roentgen ray and amplification.

INEFFECTIVENESS OF TRYPANOSOMA CRUZI ENDOTOXIN (KR) IN THE TREATMENT OF MOUSE CANCERS

Unpromising results are reported[1] in the treatment of mouse cancers with Trypanosoma cruzi. Previous comment in THE JOURNAL[2] drew attention to reports of preliminary favorable results from treatment with endotoxins of this protozoan. Hauschka and Goodwin[1] tested eight different strains of T. cruzi against five varieties of spontaneous and transplanted carcinoma and sarcoma in mice. Some inhibition of tumor growth was observed during the period of active infection by the protozoa, but normal growth was resumed when the infection was treated. The authors regarded the inhibition as not caused by specific toxins but by competition for essential dietary factors and to general depletion of the host system by the infection. Several preparations from killed T. cruzi cultures and concentrates of the organisms from mouse plasma likewise were without striking effect. Sufficient experimental evidence is not yet available to warrant this form of treatment in cancer in human beings.

ORGANIZATION SECTION

Official Note

A. M. A. OFFICIALS TO VISIT JAPAN

At the invitation of General MacArthur, five officers of the American Medical Association left August 1 for Tokyo, where they will confer with a group of medical consultants on various phases of the proposed Japanese Social Security System, including sickness insurance. The American Medical Association group will consist of President R. L. Sensenich of South Bend, Ind.; President-Elect Ernest E. Irons, Chicago; Dr. Elmer L. Henderson, Louisville, Ky., chairman of the Board of Trustees, and Drs. E. J. McCormick, Toledo, Ohio, and John H. Fitzgibbon, Portland, Ore., members of the Board of Trustees. The party took off in an Army plane from Fairfield airport near San Francisco. On arrival, the American doctors will confer with Brig. Gen. Crawford W. Sams, chief of the medical branch of the Civil Affairs Division in Tokyo. They will return to the United States within three weeks.

FIRST NATIONAL MEDICAL PUBLIC RELATIONS CONFERENCE

A national medical public relations conference, first of its kind, which will tackle six common objectives facing the medical profession will be held in St. Louis, November 27.

Public relations directors, executive secretaries charged with public relations duties and public relations committee chairmen from each of the forty-eight state medical societies will be invited to participate.

Featured for luncheon and dinner talks will be noted and qualified speakers on the following topics: "The Public Speaks on Health," "What Public Relations Did for Us" and "Yes, the Profession Needs PR."

At the workshop session which will be run in the afternoon from 2 to 5 o'clock, carefully selected discussion leaders from the state societies will grapple with these six major social issues facing the medical profession: selling the need of public relations to state medical society members, encouraging wider use of medical prepayment plans, setting up workable systems for handling night calls, the rebate problem, developing good will with labor, farm, industrial and cooperative groups, and cooperating with health agencies.

The conference will immediately precede the annual secretaries-editors meeting, which is being held in conjunction with the annual Interim Session of the American Medical Association, November 28 to December 3.

The planning and guiding of the conference will be handled by Lawrence W. Rember, William Doscher and John Bach of the Association's public relations staff.

Washington Letter

(From a Special Correspondent)

Aug. 4, 1948.

Medicine Prominent in Centennial Program

A pre-release copy of the scientific program for the American Association for the Advancement of Science centennial meeting in Washington September 14-16 discloses that medical and public health topics will be prominently featured. Participants in a symposium on world health problems will include Drs. Ernest C. Faust (Tulane), Stafford L. Warren (University of California at Los Angeles) and Leonard A. Scheele, Surgeon General of U. S. Public Health Service, as principle speakers and the following discussants: Drs. Fred L. Soper and Wilbur A. Sawyer. Dr. Thomas Parran will preside. One of the evening sessions will be on medical research, with Dr. Andrew C. Ivy (University of Illinois) as principal speaker and Dr. Lewis H. Weed, National Research Council, as chairman. Another evening meeting, devoted to psychiatry, will include an address by Dr. Kenneth E. Appel (University of Pennsylvania). Dr. Robert H. Felix, mental hygiene director of U. S. Public Health Service, will preside.

Conference of Quarantine Officers September 20-24

The most intensive conference on quarantine problems ever conducted under U. S. Public Health Service auspices is scheduled to be held in Washington September 20-24. Quarantine officers stationed at air fields where international traffic is heavy, as well as those on duty at all major ports, are being summoned here for the special meeting. The notice that has been sent to them states: "All regulatory material and technical procedures are to be reviewed in the light of the most recent advances in preventive medicine and the allied sciences. Consideration will be given to all revisions that are in the interest of the practical application of established principles of preventive medicine. The guiding purpose of the conference will be to adopt any new procedure that will give the maximum protection to our national health with a minimum restriction to the international movement of people and their goods."

Report on Health and Welfare Study Made for General MacArthur

Secretary of the Army Kenneth C. Royall has made public a one hundred and sixty-four page report evaluating current health and social security measures in Japan. It is based on an investigation, initiated at the request of General Douglass MacArthur, conducted last year by consultants from the Federal Security Agency and Federal Public Housing Authority. Charges that the mission was a vehicle of propaganda for "socialized medicine" were laid before the health subcommittee of the Senate Committee on Labor and Public Welfare in the course of its hearings last spring on the Murray-Wagner-Dingell and Taft national health bills. One of the report's major recommendations is that, for wage-earning groups now covered by various compulsory social security plans, a single system should provide for medical care as well as old age, sickness, survivors' and temporary wage loss benefits. For those groups which are not subject to an obligatory social security system, participation in voluntary prepayment plans (for medical care) should be strengthened so as to gain maximum coverage, the report states. It indorses: recognition of the public service character of hospitals, development of a nationwide system of hospitals with one over-all plan; support by public funds of the capital cost and maintenance expenses of the hospital expansion, "but as much local autonomy as possible should be permitted to encourage development of institutions suited to local needs," elevation of professional and hospital standards, adequate allocations of food to hospitals and gradual development of a midwifery service as a public function.

Examinations for Appointment in Public Health Service

Competitive examinations will be held in October for appointment in the Regular Corps of the U. S. Public Health Service in grades of assistant surgeon (first lieutenant) and senior assistant surgeon (captain). Written and oral examinations will be given. They may be taken by physicians who began internships in July of this year, on completion of which successful applicants will be placed on active duty. Application forms are obtainable from Public Health Service hospitals, district offices or by writing to: Surgeon General, U. S. Public Health Service, Washington 25, D. C.

Orientation Course on Hospital Expansion

A three week orientation course on technical aspects of compliance with the Hill-Burton Hospital Survey and Construction Act was scheduled to be concluded on July 30. Conducted by Division of Hospital Facilities, U. S. Public Health Service, the seminar was attended by architects, engineers and administrators from most of the States now participating in the federally subsidized hospital expansion program.

GOVERNMENT SERVICES

ARMY

ACUTE NEED FOR NURSES

The Army and the Air Force are acutely in need of nurses to administer to the health heeds of the 947,000 man Army and the 502,000 man Air Force authorized under the Selective Service Act by the 80th Congress. The estimated nurse strength needed by June 30, 1949 for the minimum requirements is 7,000, of which only 4,200 nurses are now on duty at stations around the world. Since the Department of the Army announced the need for nurses previously this year, 7,421 have joined the Army Nurse Reserve Corps and the Surgeon General's Office is mailing questionnaires to all of them asking whether they would accept active duty. The shortage of nurses in the Army is further shown by the 800 vacancies in the Regular Army Nurse Corps yet to be filled.

ORAL PATHOLOGY

One of the first undertakings of the recently reorganized American Registry of Pathology of the National Research Council is the fourth edition of the "Atlas of Dental and Oral Pathology" which has just been completed. The authors are Lieut. Col. Joseph L. Bernier and Col. J. E. Ash, retired, and all materials in the atlas are from files of the Institute and the Registry of Dental and Oral Pathology. The case method of presentation used in previous editions has been supplemented by a formal text which is better adapted for widespread use as a teaching medium. Sections on histology and embryology and atom bomb effects have been added.

HIGHER DEGREES FOR ARMY OFFICERS

The Department of the Army has announced that two hundred and eighty-one officers will receive academic degrees from graduate schools of civilian educational institutions in the school year now ending. These officers will receive master's degrees, or the equivalent, in their respective fields of study in institutions of higher learning throughout the country. Among the fifteen who are members of the Medical Department, seven will receive the degree of Master of Public Health, five Master of Science, one Master of Hospital Administration, one Ph.D. (Psychology) and one Master of Business Administration. Seventy-three officers of the combat arms will receive master's degrees in various fields; also one hundred and fifty engineer officers. Such advance training enables qualified personnel to keep pace with developments in medicine, engineering, business administration, personnel management and the sciences as military requirements dictate.

At the same time the Medical Department announced that nine medical officers have been certified since April by the American Boards as specialists. These officers are: Cols. Daniel J. Sheehan and James O. Gillespie, Lieut. Col. Wilbur C. Berry, and Major John D. Ashley Jr., all in internal medicine; Cols. Clinton S. Lyter and Sam F. Seeley and Lieut. Col. David Gold, all in general surgery; Cols. Frank Pinger and Edgar L. Olson in otorhinolaryngology.

PERSONAL

Major Gen. Albert W. Kenner, formerly chief medical officer at Supreme Headquarters, American European Forces, has been named president of the Army Personnel Board to succeed Major Gen. Robert S. Beightler, who becomes commanding general of the 5th Armored Division in Arkansas.

Lieut. Col. L. A. Bilotta, who entered the service as a first lieutenant in 1939, has resigned from the Medical Corps.

GRADUATE TRAINING FOR KOREAN NURSES

The Surgeon, United States Army Forces in Korea, Colonel C. P. Ward, has instituted graduate training courses for Korean nurses and doctors to promote a better understanding between organized medicine in Korea and the American occupation medical forces. On June 30 at a ceremony at the 34th General Hospital in Korea certificates were presented to twenty-one nurses from various Korean hospitals, comprising the first class to finish the postgraduate training courses. The class was addressed by General John B. Coulter, deputy commander of the United States forces in Korea.

NAVY

NAVAL AIR RESERVE NEEDS DOCTORS

Doctors who served in the Navy during the past war and who still hold reserve commissions are requested to apply for two weeks annual training duty or up to five months extended duty at Naval Air Stations, Rear Admiral Richard F. Whitehead, Chief of Naval Air Reserve Training announces.

Naval Reserve medical officers who can possibly spare the time are urged to apply for this duty to help alleviate the load at stations which are undermanned. Applications are made via the commanding officer of the air station to the commandant of the naval district concerned. The naval air stations at the following locations need assistance: Akron, Ohio; Atlanta, Ga.; Columbus, Ohio; Dallas, Texas; Denver; Glenview, Ill.; Grosse Ile, Mich.; Los Alamitos, Calif.; Memphis; Miami; Minneapolis; New Orleans; New York; Oakland; Olathe; Squantum, Mass.; St. Louis; Willow Grove, Pa.; Anacostia, D. C.; Jacksonville, Fla.; Norfolk, Va.; Seattle, and Lakehurst, N. J. Medical officers who request active duty for one year or more are eligible for additional pay of $100 per month over and above regular pay. Officers qualified in aviation medicine are especially desired. However, medical officers on active duty can apply for the five month course at the School of Aviation Medicine at Pensacola, Fla., eventually leading to the designation Naval Flight Surgeon. Quarters are available at some stations and medical officers in the Naval Air Reserve cannot be transferred without consent.

OFFICERS REQUEST POSTGRADUATE TRAINING

The Advisory Board of the Bureau of Medicine and Surgery recently approved the following Naval Medical Officers for postgraduate training:

Comdr. John G. Feder, Electrocardiography at Emory University School of Medicine, Atlanta, Ga.

Comdr. Robert A. Freyling, Residency in Orthopedic Surgery, Naval Hospital, San Diego, Calif.

Comdr. William J. James, course of instruction in Neurosurgery, Yale University Postgraduate School, New Haven, Conn.

Comdr. Roger D. Sherman, Residency in Psychiatry, Naval Hospital, Philadelphia.

Comdr. Robert B. Simons, course of instruction in Dermatology and Syphilology, Harvard Medical School.

Lieutenant Commander Harold R. Scanlon, Residency in Surgery, Naval Hospital, Long Beach, Calif.

Lieut. Comdr. William A. Wulfman, Fellowship in Radiology, New York Hospital, New York.

Lieut. Robert F. Meeko, Residency in Obstetrics and Gynecology at a Naval hospital.

Lieut. (jg) Edward G. Haskell, Residency in Surgery, Naval Hospital, Long Beach, Calif.

Lieut. (jg) Vincent C. Lowery, Residency in Psychiatry, Naval Hospital, Bethesda, Md.

RETIRED CAPTAINS VOLUNTEER

Four captains in the Navy Medical Corps on the retired list have voluntarily requested recall to active duty to aid in relieving the shortage of medical officers. They are Captains James F. Terrell, Tucson, Ariz.; Francis D. Walker, Brunswick, Maine; Arthur J. White, Toledo, Ohio, and John R. White, Lynn, Mass. Captain Terrell has been nominated for duty at the Naval Supply Depot, Long Beach, Calif., Captain Walker to the Naval Station, San Diego, Calif., Captain Arthur White to the Naval Hospital, Bethesda, Md., and Captain John White to the Sixth Naval District, Charleston, S. C., for duty as assistant district medical officer.

PERSONAL

Capt. Frederick L. McDaniel, now on duty at the Bureau of Medicine and Surgery, has been designated by the Secretary of State as a delegate to the Internation Congress on Mental Health to be held in London, England, August 11-21.

Capt. Vernal G. Backman, MCR, of Seattle, Wash., is returning to active duty with the Navy from inactive reserve status and will report for duty at the Shipyard, Bremerton, Wash.

Rear Admiral Dallas G. Sutton (MC), Retired, has been associated with the American Hospital Association, Chicago, since his retirement from the service.

Lieut. (jg) Frederick W. George III, U.S.N.R., of Buryetts-town, Pa., has been assigned to active duty at the Naval Hospital, San Diego, Calif., and Lieut. (jg) Winton R. Boyd, U.S.N.R., has been assigned to active duty at the Naval Hospital, Oakland, Calif.

NEW REGULAR OFFICERS

The following men have accepted appointments as lieutenants (jg) in the Regular Navy Medical Corps: William L. Hall, Whitesboro, Texas; Warren L. Jones, Portland, Ore.; Michael S. Lazzopina, New York; Richard W. McLean, Portland Ore., and Alfred P. Peretti, Louisville, Ky.

Lieut. Arvin T. Henderson of Ridgeville, Ind., and Lieuts. (jg) Walter F. Hansen of Union City, N. J., and Livius L. Lankford of Cisco, Texas, transferred from an active reserve status to the regular medical corps.

Comdr. F. Gowen of Philadelphia, now on duty with the Air Forces, Atlantic Fleet, has been transferred from the active reserve to the Medical Corps of the Regular Navy.

PUBLIC HEALTH SERVICE

EXAMINATION FOR THE REGULAR CORPS

An examination for appointment in the Regular Corps of the Public Health Service in the grade of assistant surgeon (first lieutenant) and senior assistant surgeon (captain) will be held in October. The written examination will be conducted October 4, 5 and 6 at places convenient to the candidates. The oral examination will be held at various points throughout the country.

Applicants must be at least 21 years of age and citizens of the United States, must present a diploma from a recognized medical school and pass a physical examination performed by Public Health Service officers.

Physicians beginning internship on July 1, 1948, will be admitted to the examination. Successful candidates will be placed on active duty in the Regular Corps on completion of internship on July 1, 1949.

Applicants for the grade of assistant surgeon must have had at least seven years of educational and professional training or experience, exclusive of high school. Applicants for the grade of senior assistant surgeon must have had at least ten years of educational and professional training or experience, exclusive of high school.

Entrance pay for an assistant surgeon with dependents is $5,011 a year and for senior assistant surgeon with dependents $5,551 a year including the additional pay of $1,200 for medical officers, as well as subsistence and rental allowance. Provisions are made for promotions at regular intervals up to and including the grade of senior surgeon (lieutenant colonel) and for selection for promotion to grade of medical director (colonel) at $9,751 a year. Retirement is authorized at either completion of thirty years' service or at the age of 64.

Application forms may be obtained from Public Health Service hospitals, district offices or by writing to the Surgeon General, United States Public Health Service, Washington 25, D. C.

THE 150TH ANNIVERSARY

The United States Public Health Service celebrated its one hundred and fiftieth anniversary July 16. President John Adams in 1798 signed a law which established the marine hospital service, forerunner of the present Public Health Service as it has been known since 1912. From a modest beginning on the Boston waterfront where sick and injured seamen could be rowed from their sailing ships to a small hospital on Castle Island, the service has grown until it now operates 25 hospitals, 115 outpatient clinics, 16 major quarantine stations, a leprosarium, 2 hospitals for drug addicts and a large research center at Bethesda, Md. Public Health Service personnel are now on duty in many of the states and in various parts of the world. The record of the service accounts for some of the most important medical discoveries: Goldberger discovered that pellagra is associated with diet; Alice Evans first identified undulant fever and proved that Bang's disease in cattle is caused by the same organisms; Rolla Dyer discovered that typhus is transmitted by rat fleas. A number of scientists of the Public Health Service have lost their lives in research on such diseases as scrub typhus, yellow fever, meningitis, Rocky Mountain spotted fever and psittacosis. The Public Health Service at present is undertaking the construction of a much larger research center at Bethesda, Md.

MISCELLANEOUS

SUMMER COURSES IN REHABILITATION

The Office of Vocational Rehabilitation, Washington, D. C., announces summer courses in rehabilitation at the following institutions: Michigan State Normal College, Ypsilanti, Mich.; Pennsylvania State College, State College, Pa.; University of Washington, College of Education, Seattle; Hampton Institute, Hampton, Va.; Colorado Agricultural and Mechanical College, Fort Collins. The work in general embraces courses in testing and guidance, educational statistics, advanced adjustment counseling and public relations in vocational education, all designed to meet the needs of personnel in state rehabilitation agencies and state agencies for the blind. Vocational rehabilitation, as provided by the states with the assistance of the federal government, aims to preserve, restore or develop the ability of disabled persons to work for pay and is primarily a service for civilians. While most veterans of the armed services have the benefit of special legislation to help overcome their disabilities, veterans are not excluded from services under the civilian program.

INDUSTRIAL SAFETY CONFERENCE

The President's Industrial Safety Conference will be held in Washington, D. C., September 27-29. The U. S. Department of Labor is in charge of planning for the conference, which will seek a nationwide solution for preventing work injuries and deaths.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

CONNECTICUT

General Practitioners.—Permanent officers of the Connecticut chapter, American Academy of General Practice, will be elected at the annual meeting in September during the Connecticut Clinical Congress. The announcement was made recently by Dr. Michael W. Palmieri, New Haven, acting secretary of the group.

Consultants for Tumor Clinics.—The Association of Tumor Clinics, in cooperation with the medical advisory committee of the Connecticut Cancer Society, has undertaken a statewide project to bring medical leaders to regular conferences of individual clinics. The consultant, who may be requested by the clinic, will be at its disposal to help with problems of diagnosis and treatment or for discussion on general principles in the consultant's field. Engagements are being scheduled through Dr. Robert Tennant, Hartford, secretary of the association. Panel constituents, approved by the association's executive committee, are: surgeons: Drs. Samuel C. Harvey, New Haven; Edward J. Ottenheimer, Willimantic; Ashley W. Oughterson, New Haven; Max Taffel, New Haven; John O. Vieta, New York, and N. William Wawro, Hartford; gynecologists: Drs. Carl E. Johnson, New Haven; Louis F. Middlebrook, Hartford, and Arthur H. Morse, New Haven; urologists: Drs. Philip M. Cornwell, Hartford, and Chris H. Neuswanger, Waterbury; radiologists: Drs. Gilbert W. Heublein, Hartford; Arnold H. Janzen, New Haven; Ralph T. Ogden, Hartford; Berkley M. Parmelee, Bridgeport, and Hugh M. Wilson, New Haven.

ILLINOIS

Film on Poliomyelitis.—The National Institute for Infantile Paralysis has awarded a $12,000 grant to the University of Illinois' Division of Services for Crippled Children for making a recording of a film on poliomyelitis. This film, entitled "Nursing Care of Poliomyelitis," was shown publicly for the first time at the First International Congress on Poliomyelitis in New York City on July 12-17.

Clay County Hospital Underway.—Ground-breaking ceremonies, marking the beginning of construction of the Clay County Memorial Hospital, were held at Flora, June 11, with Dr. Roland R. Cross, state director of public health, turning the first spadeful of earth. This is said to be the first hospital in the Middle West to be constructed from start to finish with state and federal aid as provided by the state and federal Hospital Construction Acts. The one story, fireproof building will provide fifty beds. Other speakers at the ceremony were Dr. Joseph W. Mountin, assistant Surgeon General, U. S. Public Health Service, Washington, D. C., and Dr. Norton W. Bowman, Flora, of the Clay County Medical Society.

Chicago

Appoint Director of Atmospheric Institute.—John P. Marbarger, Ph.D., of the University of Vermont College of Medicine, Burlington, Vt., has been appointed associate professor of physiology and director of research for the University of Illinois' new Aero Medical and Atmospheric Institute. Dr. Marbarger was assigned to the U. S. Air Forces' aeromedical laboratory at Wright Field, Dayton, Ohio, from 1943 to 1946. During that period he conducted research on pressure breathing and thermal regulation under extreme environmental stress. Marbarger now serves as assistant professor of physiology at the University of Vermont. He is a graduate of Lebanon Valley College, Annville, Pa., and Johns Hopkins University, Baltimore.

Victor Guillemin Jr., Ph.D., chief of the physics unit of the U. S. Air Forces' aeromedical laboratory at Wright Field, Dayton, Ohio, has been appointed biophysicist at the institute beginning July 1. He is a graduate of the University of Wisconsin, Madison, Harvard University, Cambridge, Mass., and the University of Munich, Germany, and has taught at Wisconsin, Harvard, and Massachusetts Institute of Technology, Cambridge. The institute will be equipped with apparatus for the study of aviation medicine and the study of cold, heat and barometric changes of the body.

Loyola University Appointments.—Thirteen men have been recently appointed to the faculty of the Stritch School of Medicine of Loyola University. Elinar Leifson, Ph.D., formerly on the staffs of Johns Hopkins University School of Medicine, Baltimore, and the University of South Dakota School of Medical Sciences, Vermillion, is now the new chairman of the department of bacteriology, and Martin B. Williamson, Ph.D., who has been engaged in research work at Harvard Medical School, Boston, has been named assistant professor in biochemistry. Additions to the department of anatomy are: Leslie A. Emmert, B.A., and Harold D. Fish, M.S.; new members of the department of urology are Dr. Rocco V. Serritella and Dr. Edward T. Wilson. The department of medicine has added Drs. John M. Dudek, Gould A. Andrews Jr., Albert G. Denten, Charles W. Pfister and Walter J. Kawula. Dr. George T. Stanton and Dr. Frederick R. Schwartz have been appointed to the department of neuropsychiatry and that of dermatology respectively.

Poliomyelitis Team Available for Assistance.—The Northwestern University Medical School's poliomyelitis team, headed by Dr. Emil D. W. Hauser, assistant professor of bone and joint surgery, is on call to aid poliomyelitis-stricken communities anywhere in the United States. The crew is assigned to duty and its expenses paid by the National Foundation for Infantile Paralysis. This is the crew's fourth summer of duty. Last year it served in Boise, Idaho, and before that in Rockford and Peoria, Ill. Its functions include medical consultation to doctors of the community, teaching local hospital nurses bed posture for patients and the administration of hot packs; instruction in physical therapy technics of muscle reeducation, and general functional exercises. The crew is prepared to stay on duty up to six weeks until its work in organization, teaching and medical assistance is completed. After that, the assistant orthopedist in the team remains in the stricken community as long as he is needed. Members of the 1948 team, in addition to Dr. Hauser, are Dr. Arthur F. Abt., associate professor of pediatrics; Dr. Erwin J. Cummins, orthopedist; Miss Meredith Nordschow, instructor in physical medicine; Miss Anne Prochaska, chief physical therapist, and the Misses Bernice Gotaas and Lucille Kurzawa, physical therapists. The other three teams operating under the National Foundation are those at Stanford and Harvard Universities, and the D. T. Watson School of Physical Therapy, Leetsdale, Pa.

LOUISIANA

Personal.—Dr. Charles M. Goss, professor of anatomy, Louisiana State University School of Medicine, New Orleans, has been elected editor-in-chief of the *Anatomical Record.*

Dr. Frye Comes to Tulane.—Dr. William W. Frye, professor and head of the department of preventive medicine and public health at Vanderbilt University School of Medicine, Nashville, Tenn., has been appointed professor of tropical medicine and public health and assistant director of the division of graduate medicine at Tulane University of Louisiana School of Medicine, New Orleans, effective July 1. Dr. Frye has been connected with Vanderbilt since 1931 and has been head of the preventive medicine department since 1945.

MICHIGAN

Examination of School Children.—Medical examination was given almost 40,000 school children, two thirds of all students entering high school, intermediate or elementary school, by private physicians in the joint plan of the Wayne County Medical Society and the Detroit Department of Health. The society reports that there is still need for giving more attention to visual, hearing and dental defects.

Tuberculosis Death Rate.—Tuberculosis dropped from seventh to eighth place among Michigan's ten leading causes of death in 1947, according to provisional figures released by the state department of health. In 1947, deaths from tuberculosis numbered 1,100 among males and 543 among females. More than half of the females who died of tuberculosis were under 35 years of age, while 80 per cent of the males who died were over 35 years of age. Of the 1,643 who died from tuberculosis last year, 45 were children under 5 years of age and of these, 18 were of infants less than 1 year of age.

Report of Children's Fund.—In its annual report for 1947, the Children's Fund of Michigan states that it distributed $752,910.24 for the benefit of children. About three fourths of the disbursements were made by departments created and managed by the fund in the fields of physical and mental health and medical research. The largest outlay was for child health, a total of $269,876.15 for its dental and eye programs and maintenance and service in the Northern Michigan and Central Michigan Children's Clinics, which served 8,062 children. The expenditures of the Division of Research were $140,801 for the study of nutrition, arthritis and virus. The grants-in-aid for child guidance included $4,500 to the Student Aid Foundation of Detroit, $1,000 to the Michigan Society for Mental Hygiene, $2,500 to Atlanta University School of Social Work, $3,000 to Oakland County for treatment of delinquent children in boarding homes and $2,500 to the Edith Thomas Book Project at the University of Michigan Library. Gifts to recreational agencies totaled $55,100. Children's Fund was established on May 1, 1929, by the late U. S. Senator, James Couzens, with gifts of $12,000,000, all of which must have been used for the benefit of children at the end of twenty-five years. The total assets of the fund at the close of its nineteenth year were $4,779,162.

MINNESOTA

Personal.—Dr. Wesley W. Spink, professor of medicine, University of Minnesota Medical School, Minneapolis, has been invited to address a meeting of Central and South American physicians at Cordoba, Argentina, late in November on the treatment of brucellosis recently developed in the university's medical laboratories. Dr. Spink is chairman of the subcommittee on public health aspects of brucellosis, National Research Council.——Dr. Philip K. Arzt, St. Paul, assistant clinical professor of neuropsychiatry, University of Minnesota Medical School, Minneapolis, has been appointed senior consultant in electroencephalography.

MISSISSIPPI

State Society Honors Dr. Little.—Dr. William L. Little, Wesson, a practitioner in Copiah County since 1888, was selected as the outstanding general practitioner of Mississippi by the council and house of delegates of the Mississippi State Medical Association at its meeting in May. He is a past president of the Mississippi State Medical Association, the organizer and for fifteen years director of the Copiah County Health Department, a member for four years of the state board of health and physician and surgeon for the Illinois Central Railroad for more than fifty years.

Research at the University.—Grants totaling $29,590 have been awarded to three University of Mississippi, University, faculty members in the school of medicine. Dr. Arthur C. Guyton, chairman, department of experimental medicine, received $16,000 from the Chemical Corps of the Department of the Army for a study of dust particles in the air and $4,000 from the National Foundation for Infantile Paralysis for a study of the basic physiology of pain in poliomyelitis. Sigwin B. Raska, Ph.D., assistant professor of pharmacology, was given $3,990 by the American Life Insurance Medical Research Fund for research on "Metabolism of the Kidney in Renal Hypertension." The Cancer Control Branch of the National Advisory Cancer Council awarded Dr. John D. Reese, chairman of the department of pathology, $5,000 as a cancer teaching service grant for coordination and improvement of instruction in the field of neoplastic disease.

NEW JERSEY

Hunterdon County Hospital-Health Center.—Plans have been made for a Hunterdon County hospital-health center under the auspices of an approved Eastern medical school. A hundred bed hospital is contemplated, as well as the usual health center facilities and a nurses' training school. Under the Hill-Burton act, the federal government will probably contribute one third of the funds. A recent survey showed that Hunterdon is the only county in the state without a general hospital; it has no medical or surgical specialists, and 85 per cent of the medical practitioners have no hospital connections.

Prudential Appoints Associate Medical Director.—Dr. Ronald F. Buchan, clinical director, Yale University School of Medicine Institute of Occupational Medicine and Hygiene, New Haven, Conn., has been appointed associate director of the Prudential Insurance Co. to succeed Dr. Joseph F. Sadusk Jr., Newark, who resigned to become executive director of the committee on medical sciences, Research and Development Board, Washington, D. C. Dr. Buchan, a graduate of McGill University Faculty of Medicine, Montreal, 1942, entered the U. S. Public Health Service in 1943, where he was for a time assigned to the Office of the Surgeon General of the Army as a specialist in industrial toxicology and dermatology. He also served as chief of the medical unit of the Bureau of Industrial Hygiene of Connecticut. At New Haven he was also associate physician at Grace-New Haven Community Hospital-University Service.

NEW YORK

Personal.—Dr. Amos O. Squire, Ossining, retired May 31 as medical examiner of Westchester County, a position which he has held since the office was created in 1925.—Dr. Clyde L. Randall, Buffalo, was recently appointed to membership on the New York State Board of Medical Examiners, succeeding Dr. James K. Quigley, Rochester, who has resigned after a long tenure.—Dr. James H. Lade, Albany, has been appointed director of the Bureau of Venereal Disease Control of the New York State Department of Health. Dr. Lade, a graduate of Syracuse University College of Medicine, 1934, joined the health department in 1938.

Arthritis Research in Buffalo.—The Weed Foundation has contributed $10,000 for research to Dr. L. Maxwell Lockie, professor of therapeutics, University of Buffalo School of Medicine; the fund will be used by him, Dr. John H. Talbott, professor of medicine, and other members of the Arthritis Clinic of the Buffalo General Hospital. The Weed Foundation was established in 1942 by Shelton Weed, president of Weed & Company, primarily for the care of sick and needy employees. Under the grant a research fellowship will be held by Dr. Bernard M. Norcross, a member of the staff of the Arthritis Clinic for eight years. Drs. Harold M. Robins and Clyde W. George, also members of the Arthritis Clinic, and Drs. Warren R. Montgomery, George E. Miller and Charles W. Bishop will participate in the studies under the grant. The hospital's recently completed research laboratory will provide extensive biochemical and physiologic facilities for the studies. Dr. Talbott said that the project will tie in closely with the recent grant of the National Institute of Health to the medical school for the study of gout and related problems of uric acid metabolism.

New York City

Appointed to Toxicology Laboratory.—Edward D. Palmes, Ph.D., has been appointed assistant professor of preventive medicine, New York University College of Medicine, and assigned to the laboratory of industrial toxicology, initial unit of the Institute of Industrial Medicine. Dr. Palmes was formerly with the National Institute of Health, Division of Industrial Hygiene, Bethesda, Md., where he conducted research in the toxicology of beryllium and tungsten. During World War II he was with the Armored Medical Research Laboratory at Fort Knox, Ky. He will work with Norton Nelson, Ph.D., associate professor of preventive medicine in charge of the laboratory, which is the first of three to be established by the institute, as an integral part of the New York University-Bellevue Medical Center.

Industry to Help Abate the Smoke Nuisance.—Dr. Harry S. Mustard, commissioner of health, has reported that local industry has promised to spend $30,000,000 in the next four years to abate the smoke nuisance. At a meeting of the Smoke Prevention Association of America, June 7, he cited the city's three way attack against smoke: (1) the health department's inspector service that seeks to spot and correct improper methods creating the smoke nuisance; (2) long-range program of education and correction as to present equipment; (3) research by the health department. He reported that the city will spend $61,000 next year on smoke correction work and will add five to the present eleven inspectors, a civil engineer and a mechanical engineer. New York consumes 7,500,000 tons of anthracite coal, 11,000,000 tons of bituminous coal and over 1,000,000,000 gallons of oil in one year. During the last fifteen years, use of anthracite coal has decreased 28 per cent, that of bituminous has increased 46 per cent and oil users have increased 90 per cent.

NORTH CAROLINA

Hanover County Symposium.—The New Hanover County Medical Society will have its second annual Medical Symposium at Wrightsville Beach, August 20. Following are the speakers: Drs. George Crile Jr., Cleveland; Edward G. Waters, New York; John S. L. Browne, Montreal, Canada, and Harry Walker, Richmond, Va. All interested are invited.

OREGON

Course in Allergy.—The American College of Allergists will present an intensive fall instructional course in allergy at the University of Oregon Medical School, Portland, November 8-12, under the direction of Dr. J. Warrick Thomas, Richmond, Va. Clinical and didactic instruction for physicians will be presented by instructors from Oregon and elsewhere. The fee for the course is $75.

SOUTH CAROLINA

Dr. Knisely to Head Department of Anatomy.—Melvin H. Knisely, Ph.D., associate professor of anatomy at the University of Chicago School of Medicine, became head of the department of anatomy at the Medical College of the State of South Carolina, Charleston, July 1. He succeeds Dr. Arthur M. Lassek, professor of anatomy since 1933, who left to go to the Boston University School of Medicine to continue research on the brain. Dr. Knisely received his Ph.D. degree from the University of Chicago, 1936, and was a Rockefeller Foundation fellow at the Universities of Chicago and Copenhagen, Denmark.

TENNESSEE

Dr. Wilson Honored.—Dr. Owen H. Wilson, Nashville, was guest of honor at a dinner given June 3 by the Nashville Pediatric Society and attended by more than two hundred from Nashville and Middle Tennessee. Dr. Wilson was presented with a bronze plaque commemorating his long medical service, together with a testimonial volume, and a commission as an honorary colonel on the staff of Governor McCord. Among the guests were Dr. Olin West, Nashville, representing the American Medical Association, Dr. Samuel F. Ravenel, Greensboro, N. C., dean of the Southern Pediatric Seminar at Saluda, N. C., and Vice-Chancellor C. Madison Sarratt of Vanderbilt University, Nashville.

TEXAS

Foundation Receives Million Dollar Property.—The Southwestern Medical Foundation, Dallas, has been presented the $1,000,000 Halliburton Department Store building in Oklahoma City by the Southwestern Medical Corporation, formed April 29 for the specific purpose of buying the building. Directors of the corporation are: Dr. Edward H. Cary, president, Southwestern Medical Foundation; Fred F. Florence, member, board of trustees of the foundation; Harold B. Sanders, trustee of the foundation, and Fred M. Lange, vice president and managing director of the foundation. Before turning over the title to the foundation, the corporation leased the store back to Federated Stores, Inc., for thirty years. It is expected that revenue from the lease will be used to pay back the loan.

WEST VIRGINIA

Campaign for Four Year Medical School.—A campaign for a four year medical school in West Virginia has been launched by the state medical association. A subcommittee of two association groups which is at work comprises Drs. Thomas F. E. Bess, Keyser, president of the state medical association; Wade St. Clair, Bluefield, chairman of the council; Thomas G. Reed, Charleston, president-elect; D. A. MacGregor, Wheeling, chairman of the fact finding committee, and Frank V. Langfitt, Clarksburg, chairman of the legislative committee.

Sectional Surgical Congress.—The annual meeting of the West Virginia Section of the Southeastern Surgical Congress will be held September 3-4 at the Hotel Prichard, Huntington. A general invitation to attend the meeting is extended to physicians in West Virginia, Kentucky and Ohio. Dr. Gilbert F. Douglas, Birmingham, Ala., president of the Southeastern Surgical Congress, is among the speakers. Subjects to be discussed include: surgery of the sympathetic system, pericardectomy for chronic cardiac compression, the cross-eyed child, carcinoma of the breast, and postoperative pulmonary complications. Dr. Lucien A. LeDoux, New Orleans, president of the Southern Medical Association, will be the luncheon speaker, September 3, at 12:30 p. m. At the banquet Friday evening, Dr. Herbert Acuff, Knoxville, Tenn., past president, Southeastern Surgical Congress, and president-elect, International College of Surgeons, will be the speaker.

ALASKA

Program for Research in Arctic Health.—The Federal Security Administrator has announced the establishment by the U. S. Public Health Service of a field station in Anchorage, which will assist in strengthening basic health services in Alaska and initiate a program for research in Arctic health. The program is implemented by an appropriation from Congress of $1,115,000. Dr. Jack C. Haldeman will be medical officer in charge of the Anchorage station, which should be in full operation by October 1. About $715,000 of the special Alaska funds will be made available to the Territory in the form of grants-in-aid. Additional assistance will be provided by personnel recruited by the Public Health Service and assigned to the Territorial Department of Health. Plans for the future include an Arctic Institute of Health recommended by a survey group of the American Medical Association in 1947 (The Journal, Oct. 23, 1947, p. 500). The Board of Regents of the University of Alaska has offered to provide a site on its campus for the institute, which would concentrate on a study of the Arctic region and its effects on various phases of health.

GENERAL

Spanish Edition of U. S. P. XIII.—The U. S. Pharmacopeia XIII has been translated into Spanish by Dr. A. A. Moll, formerly of the Pan American Sanitary Bureau, and the manuscript is now being set into type and distributed to a selected group for proof reading. Publication is expected within about six months. This latest edition will be distributed by La Prensa Medica Mexicana, Zacatecas 21-5, México, D. F., and the retail price of the book will be $11.

Johns Hopkins Medical Association.—At a medical alumni banquet of Johns Hopkins University, honoring Drs. Helen Taussig and Alfred Blalock, Baltimore, a National Johns Hopkins Medical Association was organized with Dr. George H. Gardner, Chicago, president, and Dr. Francis H. Redewill, San Francisco, secretary-treasurer. This new organization will take active part in social meetings of the medical alumni as well as tie in with the university's activity of developing substantial funds for new buildings.

Death of Fairleigh Dickinson.—Fairleigh S. Dickinson, president of Becton, Dickinson and Company, Rutherford, N. J., died June 23 at his home. Colonel Dickinson, known for his work in the two World Wars, invented, among other things, the Yale B-D Lok and the Yale B-D Lok-Syringes. He built his company from a small beginning in 1897 to one of the largest factories making surgical instruments. His son, who served as lieutenant commander in the Navy in the South Pacific Theater during the recent war, is now in charge of the company.

WHO Headquarters.—Geneva, Switzerland, has been unanimously selected as the permanent headquarters for the World Health Organization. Regional offices were also recommended for the following areas: Eastern Mediterranean, Western Pacific, Southeast Asia (the Alexandria Health Bureau will be incorporated in WHO), Europe and Africa. The European headquarters, which would serve the war-ravaged countries, would be discontinued as soon as a satisfactory level of health had been reached. No regional office for the Americas was recommended because of negotiations to integrate the Pan American Sanitary Bureau with the World Health Organization.

Dr. McCoy Goes to Tokyo.—Dr. Oliver R. McCoy, Rochester, N. Y., has arrived in Tokyo to serve as consultant for the Japanese Institute of Public Health. The building housing the Institute of Public Health in Tokyo was constructed from a grant of $1,000,000 from the Rockefeller Foundation ten years ago. Previously Dr. McCoy was stationed in Paris as a field staff member of the Rockefeller Foundation. During the war he was chief of the Tropical Disease Control Division, Office of the Surgeon General, in Washington, D. C., during which time he served also with the National Research Council as a member of the Board for the Coordination of Malaria Studies.

Award to Pharmaceutical Manufacturer.—The Surgeon General, U. S. Navy, on July 15 awarded a certificate of achievement to the Winthrop Chemical Company, manufacturers of pharmaceutical products, in recognition of "outstanding services rendered to the Navy's Medical Department." The award was presented to Dr. Theodore G. Klumpp, president of the company, by Rear Admiral Albert H. Dearing, District Medical Officer, during a ceremony in New York City. During the war Winthrop Chemical Company was engaged in the production of antimalarials and other drugs used in the treatment of various tropical diseases. Early in the war the firm discovered a method of producing quinacrine on a commercial scale and developed another antimalarial which was considered more potent than quinacrine or quinine.

Society Elections.—At the fiftieth anniversary meeting of the Medical Library Association in Philadelphia, May 28-30, Miss Janet Doe, New York Academy of Medicine Library, was elected president; Miss Mildred R. Crowe, Medical College of Alabama Library, Birmingham, Ala., secretary, and Mrs. Edith Dernehl, Marquette University School of Medicine Library, Milwaukee, treasurer.—At the annual meeting of the Nicholas Andre Orthopedic Society in Schenectady, N. Y., Dr. Martin Dobelle, Pittsfield, Mass., was elected president, and Dr. William T. Shields Jr., Troy, N. Y., secretary.—At the fourth annual meeting of the American College of Allergists in New York the following officers were elected for 1948-1949: Dr. George E. Rockwell, Milford, Ohio, president; Dr. Jonathan Forman, Columbus, Ohio, president-elect and Dr. Fred W. Wittich, Minneapolis, secretary-treasurer.

CORRECTION

Dr. J. Edward Berk's Discussion.—The discussion by Dr. Edward Berk in the July 3 issue of The Journal, page 848, is misplaced. Dr. Berk's discussion pertains to a paper on "Carcinoma of the Pancreas" by Dashiell and Palmer which will be published in *The Archives of Internal Medicine.*

Deaths

Charles Henry Schlichter ⊕ Elizabeth, N. J.; born in Elizabeth, N. J., June 15, 1874; New York College of Pharmacy in 1893; Columbia University College of Physicians and Surgeons, New York, 1896; fellow of the American College of Surgeons and the New York Academy of Medicine; member of the Association of Military Surgeons of the United States; member of the Academy of Medicine of Northern New Jersey which in May 1946 presented him with the Edward J. Ill award; past president of the Society of Surgeons of New Jersey, Clinical Society of Elizabeth General Hospital and Union County Medical Society; served during the Spanish-American War and World War I; later held a commission as colonel in the medical reserve corps of the U. S. Army; during World War II served as chief of emergency medical service of New Jersey Civilian Defense, chairman of the Procurement and Assignment Committee for Physicians and senior surgeon consultant for the U. S. Public Health Service reserve; member of the Commission for the Blind of New Jersey from 1923 to 1926; since 1908 member of the Board of Trustees of the Free Public Library of Elizabeth, serving as president of the board for many years; president of the city board of water commissioners; served on the staffs of the Rahway (N. J.) Memorial Hospital, Newark (N. J.) Eye and Ear Infirmary and the Elizabeth General Hospital; a member of the board of trustees of the Society for the Relief of Widows and Orphans of Medical Men of New Jersey; died April 28, aged 73, of coronary thrombosis.

Josiah Morris Slemons ⊕ Los Angeles; born in Salisbury, Md., Nov. 9, 1876; Johns Hopkins University School of Medicine, Baltimore, 1901; instructor in obstetrics at his alma mater from 1901 to 1909 and associate professor of obstetrics from 1909 to 1913; professor of obstetrics at the University of California Medical School in San Francisco from 1913 to 1915; from 1915 to 1920 professor of obstetrics and gynecology at the Yale University School of Medicine in New Haven, Conn.; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; in 1917 had charge of the survey of obstetrics in France made under the sponsorship of the American Red Cross; during the next two years a major in the medical corps of the U. S. Army, stationed in France; served as chief of the staff of the Hospital of the Good Samaritan and as regional representative for Johns Hopkins and Duke University School of Medicine; an Affiliate Fellow of the American Medical Association; member of the Pacific Coast Society of Obsterics and Gynecology; fellow of the American College of Surgeons; died in the Hospital of the Good Samaritan May 24, aged 71, of tuberculous meningitis.

Gerald Randolph Allaben ⊕ Rockton, Ill.; Rush Medical College, Chicago, 1913; fellow of the American College of Surgeons; served on the staff of St. Anthony's Hospital in Rockford; for many years in charge of the tumor section of the Veterans Administration Hospital, Hines, where he died April 1, aged 58, of carcinoma of the prostate with metastases.

Arleigh Ellsworth Allenbaugh ⊕ Evansville, Ind.; Indiana University School of Medicine, Indianapolis, 1920; affiliated with St. Mary's Hospital, Protestant Deaconess Hospital and Welborn Memorial Baptist Hospital, where he died April 3, aged 52.

Edmond J. Boling, Billings, Okla.; Memphis (Tenn.) Hospital Medical College, 1903; died in Enid March 29, aged 79.

Phares William Calliham ⊕ Harrisonburg, La.; University of Tennessee College of Medicine, Memphis, 1917; also a D.D.S.; served as mayor of Harrisonburg and as county coroner; member of the parish draft board during World War II; died in Shreveport April 13, aged 68, of heart disease.

James E. Campbell, Columbus, Ohio; Starling Medical College, Columbus, 1897; died March 30, aged 71, of coronary thrombosis.

Joseph Sweet Chandler, Muncie, Ind.; University of Louisville School of Medicine, 1947; served an internship at Ball Memorial Hospital, where he died April 3, aged 24.

Carl McLaughlin Clark ⊕ Oakland City, Ind.; Indiana University School of Medicine, Indianapolis, 1927; past president of the Gibson County Medical Society; died in the Mayo Clinic, Rochester, Minn., April 4, aged 48, of Hodgkin's disease.

Bernard Anthony Cody ⊕ San Francisco; Stanford University School of Medicine, San Francisco, 1925; died in St. Luke's Hospital March 24, aged 50, of injuries received in an automobile accident.

Elmer Ledley Cohenour ⊕ Tulsa, Okla.; Northwestern University Medical School, Chicago, 1907; member of the American Urological Association and past president of the South-Central branch; affiliated with Hillcrest Memorial and St. John's hospitals; died April 6, aged 63, of coronary thrombosis.

Edward Davis, Salem, W. Va.; Miami Medical College, Cincinnati, 1908; member of the American Medical Association; for many years member of the county board of education; served overseas during World War I; died April 11, aged 71, of heart disease.

Cornelia B. De Bey, Chicago; the Hahnemann Medical College and Hospital, Chicago, 1895; formerly member of the board of education; died in Grand Rapids, Mich., April 3, aged 82, of cerebral hemorrhage.

Nicholas Dobkin ⊕ Brooklyn; Columbia University College of Physicians and Surgeons, New York, 1897; member of the Association of Military Surgeons of the United States; served during World War I; formerly on the faculty of New York Post-Graduate Medical School and Hospital, Columbia University, New York; on the courtesy staff of the Jewish Hospital, where he died April 21, aged 73, of congestive heart failure and adenoma of the colon.

James Albert Paul Duncan, Lansing, Mich.; Grand Rapids Medical College, 1906; died in Sparrow Hospital April 4, aged 68, of Hodgkin's disease.

John Francis Dunshie, Rita, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1896; died in New Orleans February 21, aged 79, of pulmonary tuberculosis and arteriosclerotic heart disease.

Gordon LeRoy Edwards, Sarasota, Fla.; College of Medical Evangelists, Los Angeles, 1945; certified by the National Board of Medical Examiners; served an internship and residency at the Orange General Hospital in Orlando; died March 29, aged 35.

Robert Lovett Emery, Winchester, Mass.; Boston University School of Medicine, 1908; died March 19, aged 68, of cerebral thrombosis.

Harold William Fay ⊕ Dilley, Texas; Washington University School of Medicine, St. Louis, 1910; died in San Antonio April 1, aged 61, of cardiorenal vascular disease with hypertension.

Charles Franklin Fisler ⊕ Clayton, N. J., Jefferson Medical College of Philadelphia, 1895; served as a member of the board of health and registrar of vital statistics in the borough; died April 12, aged 75, of coronary occlusion.

Martin Luther Flynt Sr., Meridian, Miss.; Memphis (Tenn.) Hospital Medical College, 1908; member of the American Medical Association and of the Southeastern Surgical Congress; fellow of the American College of Surgeons; served as vice president of the Mississippi State Medical Association; chief surgeon at the Riley's Hospital, where he died April 18, aged 68, of pulmonary embolus following a fractured ankle.

Harold C. Fredrickson, Buchanan, Mich.; the Hahnemann Medical College and Hospital, Chicago, 1918; affiliated with the Pawating Hospital in Niles and of St. Joseph's Hospital in South Bend, Ind.; died April 19, aged 61, of coronary thrombosis.

Luke Glenn Garrett, Austell, Ga.; Atlanta College of Physicians and Surgeons, 1902; member of the American Medical Association; past president of the Cobb County Medical Society; served as mayor; past chairman of the Cobb County Board of Commissioners of Roads and Revenue and for fifteen years a member of the board; chairman of the board of education of Austell for twenty years; past president and director of Austell Bank; surgeon of the Southern Railroad; died April 13, aged 67, of cerebral hemorrhage.

John Jacob Gasser ⊕ Loveland, Colo.; University of Illinois College of Medicine, Chicago, 1925; affiliated with the Larimer County Hospital in Fort Collins; died March 18, aged 48, of chronic nephritis, hypertension and bronchopneumonia.

Peter Francis Ghee, Jersey City, N. J.; Leonard Medical School, Raleigh, 1898; died April 6, aged 73, of carcinoma of the prostate.

Oliver Medlar Gilliland, Topeka, Kan.; University of Kansas School of Medicine, Kansas City, 1944; a medical officer in the regular navy during World War II; interned at the Naval Hospital in Pensacola, Fla.; resident physician at the Veterans Administration Hospital in Topeka; died April 26, aged 32.

Joseph Leo Gilmore ⊕ West Haven, Conn.; Yale University School of Medicine, New Haven, 1904; served as a member of the board of police commissioners and as probation officer; died in the Hospital of St. Raphael, New Haven, April 7, aged 75, of coronary occlusion.

Robert Hal Gingles, Chickasha, Okla.; University of Oklahoma School of Medicine, Oklahoma City, 1936; member of the American Medical Association; interned at the State University and Crippled Children hospitals in Oklahoma City; served during World War II; formerly director of tuberculosis control, state department of public health; an officer in the U. S. Army at the time of death; died in the Walter Reed General Hospital, Washington, D. C., March 21, aged 42, of hepatic cirrhosis, with massive gastrointestinal hemorrhage.

John F. Guthrie, Vineland, Colo.; Missouri Medical College, St. Louis, 1885; died in a hospital at Pueblo March 30, aged 89, of bronchopneumonia.

Varney Bernard Hamlin ⊕ Clinton, N. Y.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1893; served during World War I; died April 9, aged 78, of coronary occlusion.

Oscar Varnum Hefflon, Jamaica, Vt.; University of Vermont College of Medicine, Burlington, 1903; formerly member of the state legislature; served during World War I; on the staff of the Brattleboro Memorial Hospital, where he died April 21, aged 76, of pancreatitis.

Gerald Leo Higgins ⊕ Jersey City, N. J.; University of Maryland School of Medicine, Baltimore, 1915; served as a member of the city health department; on the staffs of the Bayonne (N. J.) Hospital, Greenville and Fairmount hospitals; died April 10, aged 56, of angina pectoris.

George Holmes ⊕ Gonzales, Texas; Medical Department of Tulane University of Louisiana, New Orleans, 1905; served as president of the Gonzales County Medical Society; medical examiner for Selective Service during World War I; chief surgeon at the Holmes Hospital; fellow of the American College of Surgeons; died in a hospital at San Antonio March 24, aged 66, of coronary thrombosis.

John Thomas Hopkins Hogan, Troy, N. Y.; Albany (N. Y.) Medical College, 1914; member of the American Medical Association; died March 30, aged 60, of congestive heart failure and arthritis.

Walter Alexis Hosley, Topsfield, Mass.; Harvard Medical School, Boston, 1904; member of the American Medical Association; died March 25, aged 69, of carcinoma.

Harry W. Housley ⊕ Mendota, Wis.; Milwaukee Medical College, 1912; at one time practiced in Neillsville, where he was county coroner; on the staff of the Mendota State Hospital, where he died April 2, aged 62, of coronary occlusion.

Harry Gass Humphreys ⊕ Lieutenant Colonel, U. S. Army, retired, Overbrook Hills, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1899; Army Medical School, 1905; entered the U. S. Army in 1904 and retired Feb. 4, 1920 for disability in line of duty; died March 7, aged 73.

Rollin Jefferson ⊕ Tampa, Fla.; University of Maryland School of Medicine, Baltimore, 1903; died March 4, aged 69.

Otto Earle Johnson, Paintsville, Ky.; University of Louisville Medical Department, 1904; for many years county coroner; served during World War I; died March 27, aged 65, of heart disease.

Stanley Frederick Johnson, Chicago; Northwestern University Medical School, Chicago, 1925; member of the American Medical Association; on the staff of the Ravenswood Hospital; died in the Passavant Memorial Hospital April 21, aged 50, of cerebral accident.

William Hoye Kunst, Fairmont, W. Va.; Starling Medical College, Columbus, 1891; formerly secretary of the government board of pension examiners; died March 29, aged 82, of cerebral hemorrhage.

Tiffany Lawyer ⊕ Albany, N. Y.; Albany Medical College, 1907; on the staff of the Albany Hospital; died April 12, aged 64, of coronary thrombosis.

Otto Lerch ⊕ New Orleans; Medical Department of Tulane University of Louisiana, New Orleans, 1894; formerly on the faculty of New Orleans Polyclinic; affiliated with Charity Hospital; author of a book on rational therapy; died April 4, aged 93, of myocarditis.

George Alden Lewis ⊕ Roundup, Mont.; Wisconsin College of Physicians and Surgeons, Milwaukee, 1905; member of the American Academy of Ophthalmology and Otolaryngology; past president of the Montana Academy of Oto-Ophthalmology; past president and secretary of the Musselshell County Medical Society; served during World War I; later colonel in the medical reserve corps; died April 15, aged 68, of coronary thrombosis.

Robert Ernest Lewis, Arcadia, Calif.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1891; died March 28, aged 78.

Walter E. Looney, Chattanooga, Tenn.; Meharry Medical College, Nashville, Tenn., 1912; member of the staff of the Carver Memorial Hospital; died March 31, aged 57, of heart disease.

James Maxwell Loving ⊕ Austin, Texas; University of Texas School of Medicine, Galveston, 1903; formerly city and county health officer; served during World War I; from 1921 to 1928 surgeon in the U. S. Veterans Bureau; died April 16, aged 68, of coronary thrombosis.

Leslie Clyde Lyon, Runnemede, N. J.; Medico-Chirurgical College of Philadelphia, 1898; died in Camden County Hospital, Blackwood, March 30, aged 74, of arteriosclerosis.

Frank Kane Lyon, Parsons, W. Va.; Western Pennsylvania Medical College, Pittsburgh, 1903; served as county health officer; on the staff of Tucker County Hospital, where he died April 9, aged 71, of coronary disease.

William Case Manchester ⊕ Alliance, Ohio; Western Reserve University Medical Department, Cleveland, 1898; affiliated with the Alliance City Hospital; died April 8, aged 75, of heart disease.

Liva Charles McLain ⊕ Bakersfield, Calif.; Rush Medical College, Chicago, 1915; served during World War I; affiliated with the Mercy Hospital; died April 18, aged 62, of heart disease.

Porter J. Mitchell, Rocheport, Mo.; Missouri Medical College, St. Louis, 1880; died April 21, aged 88, of bronchopneumonia.

Hjalmar Erwin Mortensbak, Great Falls, Mont.; University of Minnesota Medical School, Minneapolis, 1936; member of the American Medical Association; formerly connected with the Nicollet Clinic in Minneapolis, where he served an internship and residency at the Minneapolis General Hospital; died April 10, aged 37, of carcinoma of the small intestine.

Donald A. Nicholson ⊕ Seattle; University of Minnesota College of Medicine and Surgery, Minneapolis, 1897; past president of the Washington State Medical Association, King County Medical Society and the Washington Society for Mental Hygiene; served with the U. S. Public Health Service; died April 10, aged 73, of myocardial failure.

Hugh Gideon Nicholson, Pacific Beach, Calif.; born in Oakville, N. C., Aug. 29, 1871; University College of Medicine, Richmond, 1897; at one time a pharmacist; fellow of the American College of Surgeons; served as treasurer of the West Virginia State Medical Association for many years; at one time superintendent and surgeon in charge of the Sheltering Arms Hospital at Hansford, W. Va.; served during World War I; for many years served with the U. S. Public Health Service; died April 12, aged 76, of angina pectoris.

William Archibald Norval, Paterson, N. J.; Baltimore Medical College, 1897; member of the American Medical Association; died March 26, aged 72, of myocarditis.

Elmer J. Nodurfth ⊕ Wichita, Kan.; University of Kansas School of Medicine, Kansas City, 1919; affiliated with St. Francis Hospital; division surgeon for the Missouri Pacific lines; died April 2, aged 56, of heart disease and nephritis.

Raymond Thomas O'Neill, Minot, N. D.; Creighton University School of Medicine, Omaha, 1928; member of the American Medical Association; died March 9, aged 46.

Patrick Ira O'Rourke, Providence, R. I.; Baltimore Medical College, 1909; member of the American Medical Association; on the examining board of the Rhode Island Employees' Retirement System; a consulting physician in psychiatry to Seton Institute in Baltimore and on the staffs of the Roger Williams General Hospital, Providence, and Pratt Diagnostic Hospital in Boston; affiliated with St. Joseph's Hospital, where he died April 3, aged 67, of anemia.

Rudolph Daniel Orth ⊕ Flushing, N. Y.; Cornell University Medical College, New York, 1909; for many years police surgeon; affiliated with the Community and St. Elizabeth's hospitals in New York; formerly on the staffs of the New York Skin and Cancer Hospital in New York and consultant at the Benedictine Hospital in Kingston; died March 27, aged 60, of heart disease.

Lloyd Hoyt Patterson, San Fernando, Calif.; University of Southern California School of Medicine, Los Angeles, 1938; member of the American Medical Association; in charge of rehabilitation at San Fernando Veterans Administration Hospital; died in St. Vincent's Hospital, Los Angeles, April 5, aged 38, of pheochromocytoma of left adrenal and postoperative shock.

Frank Loren Phillips, Chippewa Falls, Wis.; Wisconsin College of Physicians and Surgeons, Milwaukee, 1911; died in St. Joseph's Hospital April 13, aged 65, of cerebral hemorrhage.

Charles Hoover Phillips, Thomasville, N. C.; Baltimore University School of Medicine, 1892; member of the American Medical Association; for many years member of the county board of education, chairman of the county welfare board and one of the founders and for many years director of the First National Bank; affiliated with the City Memorial Hospital; died April 9, aged 77, of uremia.

Ralph Edgar Potter, West Point, Ill.; Bennett Medical College, Chicago, 1913; died April 5, aged 65.

Harry Lockwood Prescott ⊕ Kennebunk Port, Maine; Medical School of Maine, Portland, 1897; past president of the York County Medical Society; died in the Maine General Hospital, Portland, April 13, aged 75, of internal hemorrhage.

Andrew Walter Prout, Columbus, Ohio; Starling-Ohio Medical College, Columbus, 1909; formerly on the faculty of his alma mater; member of the American Medical Association and of the American Laryngological Association; died in Mount Carmel Hospital April 14, aged 63, of coronary thrombosis.

Frank Wendell Putnam, Acton, Mass.; Harvard Medical School, Boston, 1901; formerly on the staff of the Newton-Wellesley Hospital in Newton; died April 13, aged 73, of rheumatic heart disease and bronchopneumonia.

Gerrit Walter Raidt, Cincinnati; University of Cincinnati College of Medicine, 1931; Norwood School physician; served on the staffs of the Bethesda, Children's and Catherine Booth hospitals; died March 18, aged 42, of pulmonary tuberculosis.

Eugene Giles Ribby ⊕ Batavia, N. Y.; State University of Iowa College of Medicine, Iowa City, 1926; past president of the Genesee County Medical Society; affiliated with Genesee Memorial Hospital and St. Jerome's Hospital, where he died April 22, aged 48, of coronary sclerosis.

Edward John Christian Sander, Steubenville, Ohio; Starling Medical College, Columbus, 1902; at one time mayor of the city and served also on the city council; affiliated with the Ohio Valley Hospital; died March 28, aged 76, of heart disease.

Philip Ephraim Schultz, Boston; Creighton University School of Medicine, Omaha, 1933; specialist certified by the American Board of Anesthesiology, Inc.; member of the American Medical Association and of the American Society of Anesthesiologists; served during World War II; died April 3, aged 37.

Raymond Jesse Seymour, Columbus, Ohio; Ohio Medical University, Columbus, 1904; for many years professor of physiology at the Ohio State College of Medicine; died April 8, aged 69, of corpulmonale and pulmonary fibrosis.

Grace W. Sherwood, St. Albans, Vt.; Woman's Medical College of Pennsylvania, Philadelphia, 1904; member of the American Medical Association; owner of the Sherwood Sanitarium; died April 11, aged 69, of carcinoma of the uterus.

Homer Isaac Silvers ⊕ Ventnor, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1903; specialist certified by the American Board of Surgery; member and past president of the American Proctologic Society; fellow of the American College of Surgeons; president of the board of health; on the staff of Atlantic City (N. J.) Hospital; died April 7, aged 67, of coronary occlusion.

Richard Gordon Simmons, Roanoke, Va.; Jefferson Medical College of Philadelphia, 1889; veteran of the Spanish-American War; for many years city coroner; died April 6, aged 83, of uremia.

Sumner Clelland Simpson, Pittsburgh; University of Pennsylvania School of Medicine, Philadelphia, 1912; member of the American Medical Association; served in the British and American armies during World War I; died in the Western Pennsylvania Hospital April 19, aged 58.

Mary Gertrude Slaughter, Chicago; University of Illinois College of Medicine, Chicago, 1920; dispensary physician at the City of Chicago Municipal Tuberculosis Sanitarium; died April 20, aged 68, of acute coronary occlusion and chronic myocarditis.

James Melvin Smith ⊕ Philadelphia; Jefferson Medical College of Philadelphia, 1907; medical director of the Presbyterian Ministers Fund; died in the Presbyterian Hospital April 19, aged 70, of hypertensive cardiovascular disease.

John James Thomas ⊕ Cleveland; born in Cleveland Nov. 18, 1868; Western Reserve University Medical Department, Cleveland, 1893; associate clinical professor of obstetrics emeritus at his alma mater; past president of the Cleveland Academy of Medicine, which in 1941 presented him with its first distinguished service medal; from 1920 to 1940 president of the Cleveland Milk Commission; formerly member of the board of health; affiliated with St. Ann's, Women's and Maternity hospitals; died in Lakeside Hospital April 15, aged 79, of carcinoma.

John Henry Thomas ⊕ Gainesville, Fla.; Jefferson Medical College of Philadelphia, 1935; interned at the James M. Jackson Memorial Hospital in Miami, where he served a residency and where he died April 9, aged 39, of acute pancreatitis.

George Jackson Tobias, Detroit; College of Physicians and Surgeons of Chicago, 1885; in 1895 received a bachelor of laws degree from the Kent College of Law in Chicago, where he served on the faculty; died April 3, aged 88, of chronic myocarditis.

Hugh Simpson Tullos, San Antonio, Texas; Vanderbilt University School of Medicine, Nashville, 1921; served during World War I; member of the American Medical Association; died March 15, aged 49, of coronary occlusion.

William Jarvie Turner, Montclair, N. J.; Long Island College Hospital, Brooklyn, 1886; also a dentist; died April 8, aged 84.

Alfred Theodore Vogler ⊕ St. Louis; St. Louis University School of Medicine, 1904; served as examining physician during World Wars I and II; on the staffs of Deaconess Hospital, Christian Hospital and Missouri Baptist Hospital, where he died April 1, aged 66, of bilateral bronchopneumonia and coronary occlusion.

Charles Henry Voorheis ⊕ Hutsonville, Ill.; Rush Medical College, Chicago, 1893; died in the Brooks Hospital, Robinson, April 16, aged 83, of arteriosclerosis.

Robert More Wallace, Algona, Iowa; Bennett College of Eclectic Medicine and Surgery, Chicago, 1906; member of the American Medical Association; served during World War I; died in a hospital at Rochester, Minn., April 15, aged 70.

Charles Abraham Wallenstein, Newark, N. J.; Columbia University College of Physicians and Surgeons, New York, 1907; associated with the Beth Israel Hospital; died in the East Orange (N. J.) Hospital April 4, aged 62, of acute hemorrhagic pancreatitis.

Frederick Chauncey Warring Sr. ⊕ Baltimore; University of Maryland School of Medicine, Baltimore, 1908; associated with the Western Maryland Railway Company; died March 4, aged 63.

Charles Albert Watkins, West Point, Miss.; Memphis (Tenn.) Hospital Medical College, 1906; died in the Flowers Hospital April 19, aged 68, of carcinoma.

John Anthony Weierbach ⊕ Quakertown, Pa.; Medico-Chirurgical College of Philadelphia, 1910; past president of the Bucks County Medical Society; fellow of the American College of Surgeons; director of the Merchants National Bank; on the staffs of the Quakertown Community Hospital in Quakertown and the Grandview Hospital in Sellersville, where he died April 17, aged 65, of coronary thrombosis.

Wilbur George Weiss, Cleveland; Ohio State University College of Homeopathic Medicine, Columbus, 1916; died April 6, aged 57, of coronary sclerosis and cholelithiasis.

Kensey Scott West, Cleveland; Ohio Medical University, Columbus, 1903; formerly probate court psychiatrist; for many years medical director for the Brotherhood of Railroad Trainmen; served on the staffs of Cleveland City and St. John's hospitals; died April 23, aged 74, of duodenal ulcer.

Clement Skolfield Wilson ⊕ Brunswick, Me.; Yale University School of Medicine, New Haven, 1931; interned at the Mountainside Hospital in Montclair, N. J.; founder of Dr. Wilson's Private Hospital; died in the Maine General Hospital, Portland, April 27, aged 42, of cerebral hemorrhage.

Alfred Maximilian Wise ⊕ Brooklyn; University and Bellevue Hospital Medical College, New York, 1909; specialist certified by the American Board of Pediatrics, Inc.; member of the American Academy of Pediatrics; for many years affiliated with the Brooklyn Jewish Hospital; died April 3, aged 65, of coronary thrombosis.

James Benjamin Woodruff ⊕ Rochester, N. Y.; Syracuse University College of Medicine, 1905; on the staff of the Park Avenue Hospital, where he died April 11, aged 67, of acute coronary infarction.

Ralph A. Woods ⊕ Los Angeles; University of Illinois College of Medicine, Chicago, 1920; served on the staff of the California Lutheran Hospital; died in Mexico City, Mexico, April 29, aged 56, of coronary thrombosis.

Curtis M. Wray, La Fayette, Ind.; Indiana Medical College, School of Medicine of Purdue University, Indianapolis, 1906; member of the American Medical Association; served during World War I; on the staffs of St. Elizabeth Hospital and La Fayette Home Hospital; died March 17, aged 71, of coronary occlusion.

Foreign Letters

LONDON

(From Our Regular Correspondent)

July 3, 1948.

The National Health Service

There has come into force in Britain the greatest revolution in the practice of medicine that has ever occurred in the world. Some regard the change as establishing a medical millenium; others, including the majority of physicians, the descent into an abyss. Medicine, like all the activities which have made England great, has for centuries progressed on an individualistic system; now it is placed on a socialistic one, though it will still be possible for those willing and able to pay for what is offered free to do so. Like those who take advantage of the scheme they will be taxed for its maintenance. They are already suffering from the crushing taxation of the war, which has been prolonged and indeed seems likely to be permanent, for the financing of the other forms of socialism due to the labor government.

On the eve of the service the Minister of Health, Mr. Bevan, has published in the medical press a message to the medical profession. He begins by saying that there have been anxieties inevitable in so great and novel an undertaking. There will not be overnight any miraculous removal of our serious shortages of nurses and others and of modern replanned buildings and equipment. On July 5 the doctor-patient relation will be freed from what should be irrelevant to it, the money factor, the collection of fees, an aspect of practice already distasteful to many practitioners. But this will not carry with it either any discouragement of scientific freedom or any unfair worsening of a doctor's livelihood. Mr. Bevan pleads for a truly national effort and for no differentiation between those who use the new arrangements and those who, for any reason of their own, do not. In a broadcast the Prime Minister, Mr. Atlee, claimed that the most comprehensive system of social security ever introduced into any country was about to start. However, he admitted the need for a high standard of production if the money paid out under the system was to maintain a high value. Of the retiring pension he said that the country needs all the help that it could get from old persons still able to work after reaching the pensionable age. By doing so they would qualify for a higher pension. The prime minister also pleaded for caution—not to expect too much at first, as we were suffering from shortages of staff and material due to the war.

Dentists Will Not Take Part in the National Health Service

The representative board of the British Dental Association has decided by an overwhelming majority not to take part in the National Health Service. The members are profoundly dissatisfied at the complete refusal of the Minister of Health to grant any of the association's basic principles in connection with the Health Service, at the hurried and incomplete way in which the remuneration negotiations were carried out and the lack of security in the present position by which a whole-salaried service can be introduced by regulation alone. A letter is to be sent to the members of the association pointing out that although the Acts have been passed, the National Health Service cannot be successful without the willing cooperation of the profession. The council of the association is satisfied that the majority of members will not willingly go into the service. The association represents 8,000 of Britain's 12,000 dentists. But there are two smaller dental societies, which decline to advise their members not to enter the service.

Cooperation of the Clergy With Doctors in the Healing of the Sick

The Council of the British Medical Association has issued a report advocating fuller cooperation between doctors and the clergy in the healing of the sick. Having discussed the subject with representatives of the Churches' Council of Healing, the British Medical Association report states that there is no ethical reason to prevent such cooperation in all cases, and especially in those cases in which the doctor thinks that religious ministrations will conduce to health and peace of mind or lead to recovery. Central liaison has been established by the appointment of representatives of the British Medical Association to attend meetings of the Churches' Council and to serve, ex officio, on its medical advisory committee. "Medicine and the church working together," states the report, "should encourage a dynamic philosophy of health which would enable every citizen to find a way of life based on moral principle and on a sound knowledge of the factors which promote health and well-being. *Health is more than a physical problem, and the patient's* attitude both to illness and to other problems is an important factor in his recovery and adjustment to life. Negative forces such as fear, resentment, jealousy, indulgence and carelessness play no small part in the level of both personal and national health." The report also recommends that the press should be prohibited from reporting the proceedings at an inquest on a person who has committed suicide, except for the name and address of the deceased and a verdict that he died by his own hand.

Russians Refuse Foreign Medical Journals

One of the results of the war was the isolation of European countries from one another which prevented the usual exchange of scientific and medical advances and, indeed, stopped all research over the greater part of the continent during the German occupation. On the other hand, work in Britain went on because she was never occupied. Hence European physicians are pathetically eager to obtain British and American books and journals. But Russia apparently is an exception. The *British Medical Journal* states that to help the diffusion of information the British Embassy in Moscow has been presenting the Central Library with certain medical journals, including the *British Medical Journal.* But recently the Ministry of Foreign Affairs informed the Embassy that the Directorate of the Central Library subscribed to British medical journals and was not interested in receiving additional copies. The receipt of these journals was stated to contravene the decree of the Presidium of the Supreme Soviet of the U.S.S.R. on the procedure to be adopted in relations with foreign states. As with the Lenin Library, the State Central Medical Library in Moscow can now be approached by foreigners only through the Ministry of Foreign Affairs. The *British Medical Journal* describes the ban as completely senseless and another attempt to keep Russian physicians in ignorance of the achievements of a decadent bourgeoisie.

Exhibition of Pediatric Surgery

In connection with a course of postgraduate lectures given at the Royal College of Surgeons on the surgery of childhood a pathologic exhibition has been arranged at the principal hospital for children in this country, the Hospital for Sick Children, Great Ormond St., London. The object is to illustrate by means of specimens, charts, photographs and color transparencies the themes of the lectures. The hospital has an unusual collection of pathologic specimens of congenital abnormalities and diseases of infancy and childhood. Thus, to illustrate Mr. MacNab's lecture on the surgery of the newborn specimens are displayed of Arnold-Chiari malformations of the cerebellum and of hydrocephalus. Another remarkable specimen in this section is of celosomus in a premature infant born in the twenty-eighth week of pregnancy and surviving for one hour. The fissure shown in the specimen extends from the manubrium sterni almost to the umbilicus. Other rare conditions shown are nonrotation of the duodenum in a child of five years, aberrant renal vessels (to illustrate Mr. Twistington Higgins' lecture on the surgery of the upper part of the urinary tract), Wilm's embryoma of the kidney extending into the inferior vena cava. Types of cerebellar tumors in childhood and their relation to the probability of survival after operation are illustrated by a chart. The roentgen appearances of Hirschsprung's disease are shown in connection with a lecture by Mr. Harold Edwards. There are exhibits of historical interest which include a volume of clinical notes by Sir Thomas Barlow and a plaster cast of Cheadle's specimen of a child with advanced rickets.

The Frequency of Premature Babies

In opening a premature babies unit at Manchester, Dr. Alan Moncrieff, professor of child health in the University of London, gave some important statistics of prematurity. At present the number of premature babies who die annually is nearly four times that of children under 15 killed on the roads. Between 5 and 6 per cent of all babies are premature, according to the international standard (below 5½ pounds [2,495 Gm.] at birth) and nearly half of these die in the first twenty-four hours. Of all babies who die in the first four weeks of life nearly half die because they are premature. Some persons asked whether it was worth keeping premature babies alive, but nobody who worked with children had any doubt. The vast majority, even those who started life at 2½ pounds (1,134 Gm.) could grow up into normal citizens. As examples he cited Voltaire, Newton and Winston Churchill. Among 1,000 premature children only 1 or 2 could be found who did not come up to excellent standard later.

The Increasing Senility of the British Population

The organization known as P. E. P. (Political and Economic Planning) has published an important report on the population of Britain. It is anticipated that in the second half of the present century the population in most of the white nations outside the "iron curtain" in Europe, the British Dominions and North America will become stationary. In the Soviet Union and its associated nations and in South America it is expected that population will grow, though tending toward a stationary position. It is held that stationary numbers in Europe afford an opportunity of greatly improving standards of living. In Britain there is no prospect of or need for a population increase. Indeed there is a prospect of a slow decline. But the thing which causes concern is the increasing senility of our population—the steady increase of the elderly and the depletion of the younger and most adaptable working age groups. A factor in the latter is emigration, at present moderate, to the Britsh Dominions. This is counteracted to some extent by immigration of young persons from Europe. But the danger of demographic senility cannot be averted without a somewhat higher birth rate between the wars.

To encourage larger families P. E. P. has a comprehensive program for mitigating the financial and social penalties to which modern life subjects parents. It holds that there should not be inducements or pressure on women to combine employment and motherhood or to choose between the two. The community should assume a larger share of the cost of child rearing which falls on parents.

The First International Students' Clinical Congress

Under the presidency of Professor J. A. Ryle the British Medical Students' Association will hold an International Congress of Clinical Medicine from July 6 to 23 successively at London, Birmingham and Oxford. About two hundred delegates from more than thirty countries are expected. The congress will consist of ward teaching, lectures, demonstrations, medical films and visits to research laboratories. There will also be visits to theaters and other places of interest.

BRAZIL

(From Our Regular Correspondent)

RIO DE JANEIRO, July 5, 1948.

Potassium and Bacterial Infections

Dr. F. Rocha Lagoa, of the Oswaldo Cruz Institute, Rio de Janeiro, published, in 1945 and 1946, two papers reporting the results of studies on the defensive role of the corticoadrenal gland in infections and on the variation of cellular permeability in immunity. He concluded that the protective function of the cortin hormone is due to its regulating the cellular permeability. Trying to advance this knowledge, he became interested in body potassium. Ability to maintain a great difference between intracellular and extracellular potassium concentration is one characteristic of living cells. If the loss of potassium to the extracellular fluids is too great, as occurs when cellular elements of the tissues are injured, the liberated potassium may cause extensive trouble, as happens in corticoadrenal insufficiency, anaphylactic shock and shock caused by hemorrhage or trauma. In these conditions symptoms similar to those of potassium poisoning are present, so much so that some authors, such as Zwemer and Truszkowsky, consider high blood potassium level as the basal factor in the syndrome of corticoadrenal insufficiency. The increase in blood potassium is followed by the decrease of sodium concentration in the body fluids. The clinical significance of these biochemical data for the diagnosis of corticoadrenal insufficiency and for the control of its treatment was demonstrated in Brazil by the work of Annes Dias and Peregrino.

This knowledge led Dr. Lagoa to infect rabbits with Klebsiella pneumoniae, Pseudomonas aeruginosa and Salmonella enteritidis. He found that during the infection the potassium content of the plasma increases almost immediately after the inoculation and stays high, when the infection is of a serious character, the concentration increasing progressively (25, 50 and even 100 per cent) until the death of the animal. When the infection is mild, the potassium level increases during the septicemic stage (about 50 per cent), but decreases as the animal overcomes the infection, gradually returning to normal. The action of the corticoadrenal hormone was tested by the use of a commercial product. In rabbits inoculated with 300,000,000 K. pneumoniae, a dose that surely would cause death within twenty-four hours, cortin injected intramuscularly or intravenously, one, five and seven hours after the inoculation, was not effective in preventing the continuous increase of the potassium level and a fatal outcome. However, cortin injected several times prevented a high level of potassium in the plasma during the development of an infection produced by injection of 150,000,000 bacteria, an amount that under normal conditions always causes death. But when cortin was discontinued twenty hours after the injection of the germs the infection increased rapidly and the animal died in a short time, with a high level of blood potassium. If cortin is given every hour until the twenty-sixth, instead of only until the twentieth hour, the potassium level in the plasma—extremely high when the hormone is no longer injected—gradually becomes lower and finally returns to normal, and the animal is cured of the infection.

Dr. Lagoa concluded that the determination of the potassium level in the plasma provides a means of ascertaining the resistance of the organism suffering from a bacterial infection, this level increasing when the infection is developing and becoming severer, or getting back to normal if the infection is being overcome. The testing of the potassium level reveals also the action of cortin on the tissues, which is found to control the permeability of the cells to potassium. He further suggests the investigation of the potassium level of the plasma in cases of virus diseases, particularly in influenza, in which the syndrome of corticoadrenal insufficiency is so frequently present.

Bureau of Investigation

SENATOR LANGER ABUSES FRANKING PRIVILEGE BY CIRCULATION OF PROPAGANDA FOR KOCH'S CANCER QUACKERY

In the *Congressional Record* for June 7, 1948, by unanimous consent, appeared an article which had appeared in a so-called Lutheran magazine known as *The Eleventh Hour.* The article bears the title "The Koch Treatment" and begins as follows:

> Fortunately for Canadian farmers in the Province of British Columbia, the Minister of the Department of Agriculture possessed an open mind . . .
>
> Such ailments as Bang's disease, Johne's disease, and other fatal diseases that customarily make devastating demands upon dairy herds, are no longer fatal in British Columbia. Thanks to the integrity and foresight of Canadian physicians, veterinarians, and Government experts who recently completed a series of successful experiments with the Koch system for treating virulent diseases.

A reprint of the extension of remarks of the Honorable William Langer of North Dakota appeared in a leaflet which bore a notation across the top: "(Not printed at Government expense)." The manila envelope in which this leaflet was distributed in the United States mails to an unknown number of Doctors of Medicine bears a notation that it was manufactured in the U. S. Government Printing Office, and the envelope and its contents were sent through the United States mails without the payment of postage. This is not the first time that the taxpayers of the United States have been called on to undergo an expense on behalf of Dr. William F. Koch of Detroit. A criminal prosecution in the federal court at Detroit involved two trials, neither of which, unfortunately, ended decisively. The first trial occurred in 1943, beginning on January 12 of that year and ending on May 28 with a hung jury. A second trial, with the same set of facts, charging the same violation of law, started Feb. 19, 1946. It ended, because of the illness of a juror, on July 24 of that year.

The "open-mindedness" of the Department of Agriculture of the Canadian province mentioned is part of the record of the 1946 trial. Such open mindedness consisted, apparently, of accepting a so-called scientific experiment conducted by a salesman for the Koch Laboratories in Canada, a veterinarian in the employ of that laboratory and a veterinarian in the employ of the Province of British Columbia, who happened, also, to be secretary of the Veterinary Association of that province. The testimony brought forth that "glyoxylide," one of the names Koch uses for his alleged cancer "cure," was administered to a number of selected cows, which showed excellent results in the reduction of fibrosis, even to the extent of the complete disappearance of fibrosis in some of the cows afflicted with mastitis. The report was then submitted to a committee who admittedly had never seen any of the cows, and that committee, acting on the information received from the three persons mentioned, issued a report on the effectiveness of the treatment. The testimony of the three "scientists"—the salesman in the employ of the Koch Laboratories and the claimed disinterested veterinarians—was followed by a member of the committee. He was a professor in veterinary science at the University of British Columbia. He admitted on cross examination that the laboratory findings in mastitis, the only disease condition in which a pretense of laboratory check was made, did not show improvement of the cows beyond the material course of the disease. He testified that the laboratory findings were discarded and clinical findings only were considered. He further admitted, with respect to complete disappearance of fibrosis, that he and other members of the committee had accepted the report of the three "investigators." He also, but rather reluctantly, admitted that if he had been misinformed of the results obtained, his conclusions and opinions expressed would also be wrong.

Would it be too embarrassing to Senator Langer, who has lent his name to this piece of pseudoscientific nonsense, if he could now incorporate in the *Congressional Record* a recital of the facts brought out in a clinical experiment conducted at Ottawa, Canada, under the observation of Dr. R. E. Valin of Ottawa and other qualified medical observers appointed by the Canadian Cancer Commission? Testimony in the trial indicated that the Canadian Cancer Commission filed a report that they had been unsuccessful in their efforts to obtain samples of Koch's glyoxylide for laboratory work but that they did receive some of the material for clinical use. Nine patients with positive results in biopsies for cancer were treated with the drug by Dr. Arnott, Koch's Canadian representative. All 9 patients were dead within a period normally expected for such cases, and in no instance was there any improvement or relief from pain. The report of the commission, which is dated Feb. 7, 1943, concluded with this statement: "A careful review of all of the evidence presented at this date fails utterly, in the opinion of the commission, to support the claim made on behalf of the Koch treatment that it is either a remedy or a cure for cancer."

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Drugs: Downing Solution as Drug or Medicine.—The plaintiffs filed an action to restrain the defendants, California State Board of Pharmacy and others, from molesting or interfering with the plaintiffs in the production and marketing of a preparation known as Downing solution. From the granting of a preliminary injunction, the defendants appealed to the district court of appeal, first district, division 2, California.

The State Board of Public Health caused the arrest of the plaintiffs on a charge of conspiracy to violate the health and safety code, which prohibits "the manufacture, production, preparation, compounding, packing, selling, offering for sale, advertising or keeping for sale within the state of California . . . of any drug or device which is adulterated, mislabeled or misbranded. . . ." The plaintiffs accordingly filed suit for an injunction to restrain the defendants from proceeding with the criminal action, their major contentions being (1) that the Downing solution was not a drug and (2) that it was not adulterated or misbranded.

The term "drug," said the court, includes all medicines for internal or external use. ". . . articles intended for use in the diagnosis, cure, mitigation, treatment or prevention of disease in man or other animals; (3) articles (other than food) intended to affect the structure or any function of the body of man or other animals" are within the scope of the term "drug" (Health and Safety Code, sec. 26200). The use of a substance, therefore, determines its classification and, if it is used for medicinal purposes, it is a drug. In determining the purpose of the manufacture, sale or giving away of Downing solution, the court continued, the evidence introduced must be considered. The complaint alleges that the preparation relieves pain and discomfort in "certain diseases." Affidavits on file set forth that the solution cured "prostate gland" trouble; that a patient took the solution internally for cancer and "had less and less pain"; that a patient was cured of dysentery; that a cancer patient is taking 75 drops a day and has improved in health, whereas another person suffering from cancer has improved with 7 drops three times a day. Several physicians appeared as witnesses, one who had administered the drug internally or externally to patients. Counsel for plaintiffs admit that the solution is in effect a "substitute for narcotics." In spite of the claim that the solution is not a drug, concluded the court, the evidence preponderates that it is used for medicinal purposes.

The plaintiffs also contended that the solution was not misbranded. Section 26244 of the Health and Safety Code provides: "A drug or device shall be deemed to be misbranded unless its labeling bears (1) adequate directions for use; and (2) such adequate warnings against use in those pathological conditions or by children where its use may be dangerous to health, or against unsafe dosage or methods or duration of administration or application, in such manner and form, as are necessary for the protection of users." According to the plaintiffs' evidence the solution has been manufactured, sold or given away and subsequently used for twenty years. However, its only label was "Downing solution." Furthermore there was no showing that the plaintiffs had complied with the legal prerequisites applicable to the selling or giving away of a "new drug." The appellate court accordingly concluded that Downing solution was a drug and that it was misbranded as marketed by the plaintiffs. It therefore reversed the order appealed from and discharged the preliminary injunction. *Downing v. California State Board of Pharmacy, 192 P. (2d) 39 (Calif., 1948)*

Charitable Hospitals: Effect of Indemnity Insurance on Liability for Negligence.—The plaintiff sued for damage for injuries sustained through the alleged negligence of the defendant, an eleemosynary corporation. From a judgment for the defendant, the plaintiff appealed to the Appellate Court of Illinois, first district, second division.

The plaintiff, a boy 5 years of age, was severely injured as the result of a fall from the unguarded roof of a wooden ticket office used as a part of the St. Philip Stadium, which was owned and operated by the defendant, Servite Fathers, an Illinois corporation, organized for religious, educational and charitable purposes. In answer to the complaint, the defendant averred that the stadium and other buildings on the premises did not constitute an attractive nuisance, denied the charges of negligence and contended that because of its eleemosynary character it was not liable to the plaintiff. By way of replication, the plaintiff admitted that the Servite Fathers was a charitable institution but argued that it was nevertheless liable because it had purchased a comprehensive general liability insurance policy wherein the insurer agreed to pay all sums which the defendant should become obligated to pay by reason of liability imposed on it for damages caused by accidents on or about the defendant's premises. Attached to this insurance policy was a special rider providing that the insurer would not use the defense of immunity of the defendant unless requested so to do. The plaintiff insisted that the provisions of this policy created a fund, separate and apart from the trust fund of the eleemosynary institution, to be used as compensation to any person who might be injured by reason of defendant's negligence in the maintenance and operation of its stadium.

The question presented, said the appellate court, is whether immunity should be granted to a charitable corporation which has protected its trust funds by carrying insurance indemnifying it against negligent injuries to others.

The appellate court pointed out that the liability of a charitable institution to respond in damages for the negligence of its servants and employees has been many times before the courts and said that such institutions have claimed exemption not only on the trust fund theory but also on the nonapplicability of the rule of respondeat superior, the waiver theory and the theory of public policy. The reason for immunity given under the trust fund theory is that the trust fund might be wholly destroyed and diverted from the purpose for which it was given, thwarting the donor's intent, as the result of negligence for which he was in nowise responsible. The theory that the doctrine of respondeat superior is not applicable to charitable institutions is founded on the argument that the rule has application only when the master derives some profit or advantage to himself from what his servant does, and since a charitable institution makes no profit from the endeavors of its servants the rule has no application to it, and therefore it is not responsible for their negligent acts. Courts adopting the waiver theory argue that one who becomes a beneficiary of the charity does so on the implied assent or condition that the trust property is not available to him for compensation in the event of his injury through the negligence of the trustees or their servants. Concerning the public policy, those supporting the theory say that it is better for the community and public in general that the individual suffer and bear his loss rather than that the offending charitable institutions should suffer in damages and so impair, theoretically at least, its ability to offer its charity on as wide a scale as possible.

Continuing, the appellate court pointed out that Illinois is listed among the states which grant unqualified immunity to charitable institutions. In the case at bar, however, the Servite Fathers wished to protect those who might be injured through their negligence by taking out a liability insurance policy which expressly stipulated that the insurer should not interpose the defense of immunity unless requested by the insured to do so. There is nothing in the record to indicate that the defendant made any such request. The immunity doctrine, continued the court, was devised for the benefit of the charitable corporation, and if the corporation wishes to waive immunity we know of no principle in law to prevent it from doing so. To hold that the exemption from liability is "absolute" and that a hospital or charitable institution may not protect its beneficiaries as well as itself by insurance because it creates a new liability where none existed is to extend the immunity doctrine beyond the cases previously decided in this state. If such an absolute immunity rule were to prevail it would seem a sheer waste of money for a charitable corporation to purchase insurance protection. We hold, the appellate court concluded, that where insurance exists and provides a fund from which tort liability may be collected so as not to impair the trust fund, the defense of immunity is not available. Accordingly the judgment in favor of the defendant was reversed and the cause was remanded for a new trial.—*Wendt v. Servite Fathers, 76 N. E. (2d) 342 (Ill. 1947).*

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

BOARD OF MEDICAL EXAMINERS
BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of the boards of medical examiners and boards of examiners in the basic sciences were published in The Journal, July 31, page 1243.

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Parts I & II.* Various centers, Sept. 13-15. Final date for filing application is Aug. 13. Exec. Sec., Mr. Everett S. Elwood, 225 South 15th St., Philadelphia 2. *Part III.* Boston and New York, Autumn. Sec., Dr. J. S. Rodman, 225 S. 15th St., Philadelphia.

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: *Written.* Various Centers, Jan. 21, 1949. Final date for filing application is Oct. 1. *Oral,* Philadelphia, Oct. 10, Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York 22.

American Board of Dermatology & Syphilology: *Written.* Ann Arbor, Sept. 9. Sec., Dr. G. M. Lewis, 66 E. 66th St., New York 21.

American Board of Internal Medicine: *Written.* Oct. 18. Asst. Sec., Dr. W. A. Werrell, 1 W. Main St., Madison 3, Wis.

American Board of Neurological Surgery: *Oral.* Chicago, June 1949. Final date for filing application is Jan. 1949. Sec., Dr. W. J. German, 310 Cedar Street, New Haven, Conn.

American Board of Obstetrics and Gynecology: *Part I.* Various Centers, Feb. 4, 1949. Final date for filing application is Nov. 1. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh 1.

American Board of Ophthalmology: *Oral.* Chicago, Oct. 6. *Written.* Various Centers, January 1949. Sec., Dr. S. J. Beach, 56 Ivie Rd., Cape Cottage, Maine.

American Board of Orthopedic Surgery: *Part II.* Chicago, January 1949. Final date for filing application is August 15. Sec., Dr. Francis M. McKeever, 1136 W. 6th St., Los Angeles 14.

American Board of Otolaryngology: *Oral.* Chicago, Oct. 5-8. New York City, Spring, 1949. Sec., Dr. D. M. Lierle, University Hospital, Iowa City.

American Board of Pathology: Chicago, Oct. 8-9. Final date for filing application is Oct. 1. Sec., Dr. Robert A. Moore, 507 Euclid Ave., St. Louis.

American Board of Pediatrics: Seattle, Sept. 10-12. Atlantic City, Nov. 17-19. Sec., Dr. Lee F. Hill, 718 Royal Union Bldg., Des Moines, Iowa.

American Board of Plastic Surgery: Examinations are given in June and November of each year in the hometown of applicants. Sec.-Treas., Dr. Louis T. Byars, 400 Metropolitan Bldg., St. Louis, Mo.

American Board of Radiology: Nov. Final date for filing application is Sept. 1. Sec., Dr. B. R. Kirklin, 102-110 Second Ave., S.W. Rochester, Minn.

American Board of Surgery: *Written.* Various Centers, March 1949. Final date for filing application is Dec. 1. Sec., Dr. J. S. Rodman 225 S. 15th St., Philadelphia.

American Board of Urology: Chicago, Feb. 12-16, 1949. Final date for filing application is Sept. 1. Sec., Dr. Harry Culver, Route #13, Sunnyside Rd., Minneapolis 4.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Cyst of Spleen. Case Report. V.F. Lang, S.A. Morton, J.D. Steele and A.A. Schaefer. -p. 572.

Transposition of the Aorta —According to Hanlon and Blalock, the time of survival in complete transposition of the aorta and the pulmonary artery in man is dependent on the degree of mixing between the greater and lesser circulations. Such mixing may be effected by interatrial or interventricular septal defects, by a patent ductus arteriosus or by entry of pulmonary veins into the transposed right side of the heart. In 123 cases of complete transposition collected from the literature the average duration of life was only nineteen months. Artificial production of pulmonary venous return to the right side of the heart was effected in dogs under anesthesia by anastomosing the pulmonary veins to the right auricle or to the superior vena cava. In 10 instances the pulmonary veins from the upper lobes of the right lung were anastomosed into the right auricle, but the results were usually unsatisfactory; it seems likely that the thick auricular wall, especially in its trabeculated area, is not well suited to vascular anastomosis. The pulmonary veins were anastomosed to the superior vena cava at the azygos opening in 15 animals; in general the results of these anastomoses were excellent, since the anastomosis remained patent in over three fourths of the experiments. Anastomosis of the pulmonary veins to the superior vena cava appears feasible in man and offers one possible approach to the surgical treatment of complete transposition of the great cardiac arteries.

Varicose Veins.—Luke and Miller report 21 cases of varicose veins showing evidence of retrograde flow in which untoward results followed the operation of high ligation and retrograde injection of the saphenous vein. Death occurred in 4 cases and deep thrombophlebitis with permanent disability in 10 additional cases, some with persistent edema, eczema and ulceration of the leg. The increasing frequency of these unfortunate results is emphasized. These disasters result from operative difficulties and mistakes and from deep venous thrombosis subsequent to operation. In the latter group the lack of muscular activity of the legs following operation, resulting in a slowing of the deep venous return, and the use of too great a quantity of sclerosing fluid probably play a considerable part in the formation of the thrombosis. It is suggested, therefore, that only a local anesthetic be used and that patients walk immediately after the operation. No more than 5 cc. of any sclerosing solution should be injected at the time of operation. If an embolus should occur, removal of the clot in the vein with ligation of the superficial femoral vein is advocated. "Dicumarol" in adequate dosage should be administered only in those cases in which ligation is not feasible. Experience may finally show that ligation alone should be carried out, with later injections once a week until the varicosities have been obliterated.

Sacrococcygeal Chordoma.—Gentil and Coley report 7 cases of sacrococcygeal chordoma in 5 men and 2 women between the ages of 50 and 70 years who were treated at the Memorial Hospital during the period 1930 to 1943. Additional 128 cases of sacrococcygeal chordoma collected from the literature are reviewed; 88 of the patients were men and 40 were women, and the median age was 46 years. The condition is rare. It occurs more frequently in men and chiefly in the age groups between 40 and 60 years. Aspiration biopsy showing the three main microscopic features, i.e., presence of intracellular and extracellular mucin, physaliferous cells and lobular arrangement of the tumor cells, is a useful and reliable method of establishing the diagnosis. Though generally considered benign, sacral chordoma metastasizes in approximately 10 per cent of the cases and causes death either directly or indirectly in nearly all instances. It is of long duration, is slow growing, yields but little to intensive roentgen therapy and is not amenable to complete surgical removal owing to its inaccessibility and extensive involvement of the pelvic organs and spinal cord. Local recurrence following surgical excision is a constant feature Pain is the most serious symptom, especially when the disease is advanced, and is difficult to control; radiation therapy is of some value especially during the late stages. A method allowing more radical surgical extirpation is needed, but radical surgery involves difficulty with regard to bladder and rectal control. These complications might be overcome by preliminary permanent colostomy and ureteroenterostomy, but these operations may well be considered unduly radical to apply for a slow-growing and relatively low grade malignant tumor It is nevertheless the authors' opinion that surgical excision should be attempted whenever a recurrence occurs even though there is a little likelihood of complete removal; cases in which there were long term survivals were essentially treated by repeated surgical excisions.

Cholesterol and Arteriosclerosis.—Evidence is accumulating that certain persons possess an inherently defective mechanism for metabolizing cholesterol. These subjects may resemble the rabbit, a species in which there develops atherosclerosis quite uniformly if cholesterol is fed. Conversely, other persons may be more similar in this respect to the rat, in which feeding of cholesterol does not produce atherosclerosis. The discovery of certain lipotropic substances which will mobilize lipids from the liver has suggested that these same substances might be effective in mobilizing cholesterol from atherosclerotic arteries or, more likely, in preventing the deposition of the lipoid in the vessels of those who are predisposed to hypercholesteremia. Hermann found what he regards as a significant effect from substances like choline, methionine and inositol

Total Pancreatectomy.—Gaston reports the case of a man aged 70 who was subjected to a total pancreatectomy on account of diffuse carcinoma of the organ. Similar cases reported in the literature are analyzed. The surgical mortality of total pancreatectomy is high, but with increasing experience the surgical mortality can probably be reduced to acceptable limits. The diabetes that follows total pancreatectomy is relatively mild and appears to be associated with an increased insulin sensitivity. Hypoglycemic reactions, which may be severe or even fatal, should be avoided. Early treatment of the diabetic state should be directed toward the prevention of ketosis rather than the rigid control of blood sugar levels. The fatty liver associated with total pancreatectomy in dogs has not been observed in man, but prevention of this disorder can probably be effected by a diet rich in choline. Because of the poor digestion of fat in the total absence of pancreatic secretion the stools tend to be bulky and frequent. The postoperative diet should be low in fat, the caloric intake being made up with carbohydrates, which are well tolerated. In addition, pancreatin in doses of 15 Gm. daily should be administered to increase the absorption of fat and protein and to aid in maintenance of nitrogen equilibrium.

Presacral Neurectomy for Dysmenorrhea.—Ingersoll and Meigs say that at Massachusetts General Hospital and Palmer Memorial Hospital a total of 111 presacral neurectomies have been performed for relief of dysmenorrhea during the years from 1930 to 1946. In most cases the neurectomy was combined with dilatation and curettage, a suspension and any other necessary pelvic surgical measures that the gynecologic situation demanded. These 111 cases can be divided into a group with essential dysmenorrhea and a group with acquired dysmenorrhea. The patients in the former group had severe crampy pain starting shortly after the menarche, with painful menstruation that severely upset their social and economic life; physical examination was negative. The patients with acquired dysmonorrhea had pathologic processes to explain the painful periods. Complete relief was obtained in 81 per cent of cases of essential dysmenorrhea and 52.6 per cent of acquired dysmenorrhea. There were 12 therapeutic failures after presacral neurectomy for essential dysmenorrhea. These failures are accounted for on the basis of either regeneration of sympathetic nerves, incomplete operation or dysmenorrhea as a manifestation of a psychoneurosis. Twenty-four women had babies postoperatively; labor was painless for 8 of them.

BCG in Prevention of Tuberculosis.—Aronson shows that despite the fact that BCG vaccine has now been in use throughout the world for twenty-five years, there exists some opposition to its universal use. This opposition is based primarily on the supposition that the culture might revert to its original virulent state and induce progressive lesions and, second, on the view that the protective value of the vaccine has not, thus far, been definitely established. There is no unequivocal evidence that BCG vaccine has ever produced progressive tuberculosis in man. Freshly prepared BCG vaccine suspended in isotonic sodium chloride solution was injected intracutaneously into 1,550 American Indians of varying age who were tuberculin-negative. At the same time 1,457 Indians who were tuberculin-negative and comparable in age and economic background received an intracutaneous injection of isotonic sodium chloride solution and served as controls. No untoward local or general reactions were observed following vaccination. Both the vaccinated subjects and the controls were followed over a period of nine to eleven years by means of annual tuberculin tests and roentgenograms of the chest. During the period of observation 55 of the 1,550 vaccinated persons died from all causes, including 6 who died from tuberculosis. Among the 1,457 controls, 108 died from all causes, including 52 deaths from tuberculosis. The author concludes that the use of BCG vaccine does materially reduce the morbidity and mortality from tuberculosis.

Cirrhosis of Liver: Response to Treatment.—Morrison attempts to clarify and evaluate the conditions under which cirrhosis of the liver can be expected to improve. He outlines a combined intensive treatment which consists of a maximum protein (three meat servings daily plus skimmed milk), high carbohydrate, low fat diet, daily injections of 5 cc. of a "whole" liver extract, highly potent injections of vitamin B complex, daily oral vitamin B complex, and multiple "total" vitamin capsules orally, together with 2 Gm. each of methionine and choline daily. He compares the results of this treatment on 20 patients (11 without ascites and 9 with ascites) with the results obtained in 23 patients who were treated only by such methods as were in use in 1938, that is, by paracentesis, diuresis, high carbohydrate diet and palliative therapy; this group of 23 contained 11 cases without ascites and 12 with ascites, and was called the "untreated" group. After two years all patients in the treated group without ascites were alive, as compared with a 27 per cent mortality rate in the control series. Excellent therapeutic results occurred in those patients with the alcoholic type of cirrhosis of the liver, i.e., the fatty or portal, Laennec's cirrhosis, in the early or moderately advanced stages. In the terminal form of the atrophic portal cirrhosis, with a shrunken liver, the therapeutic regimen frequently gave indifferent results or was a complete failure.

Cytologic Method in Gastric Carcinoma.—Graham and her associates present the results obtained with the cytologic technic on gastric aspirations from 50 patients suspected of having cancer of the stomach. A fasting specimen of gastric secretion is obtained by aspiration. Gastric aspirations were used rather than gastric washings. It is of the utmost importance that the specimen be sent to the laboratory immediately, since if there is more than half an hour's delay the cells are digested and no distinct cellular characteristics can be identified. The specimen is centrifuged immediately, the sediment spread on a glass slide and placed at once in a fixative of equal parts ethyl ether and 95 per cent alcohol. After fixation for at least fifteen minutes, the slides are stained by Papanicolaou's method. The malignant cells often appear in groups; they have nuclei which are hyperchromatic and usually contain prominent nucleoli. Often the cytoplasm shows vacuolization, a characteristic of adenocarcinoma. There are occasional single cells which can be identified as malignant. In this series of 50 patients, 24 had carcinoma of the stomach. Cancer cells were seen in the gastric fluid of 15. All 24 of these patients were explored. Seven of the lesions were resectable, and 5 of these had previously shown malignant cells in the gastric secretion. One of the 2 failures in this small group involved a scirrhous carcinoma of the wall of the stomach without ulceration of the mucosa. Such a tumor could not be expected to shed cells into the gastric lumen. Although 9 of the 24 cases of carcinoma in this series were erroneously called negative on cytologic examination, only 2 of the 7 resectable cases were missed and 2 extremely early cases were both diagnosed correctly. The authors believe that the cytologic method is of great value in the detection of gastric cancer.

Ovarian Pain and Insufficiency.—Heckel divides his cases into 3 groups. In the first group of 15 cases ovarian tissue had been previously removed, in most instances because of pain in the lower part of the abdomen. Pain recurred following operation, and when the patients came under observation of the author its source could be identified as the ovary. The second group of 75 patients were observed before surgical intervention was performed. In all of them observation revealed the ovary to be the source of the pain and in none was it of sufficient cyclic regularity to be classed as mittelschmerz. Cases of cyclic intermenstrual pain or mittelschmerz comprise the third group of 25 cases. The author stresses that the frequent association of pain with menstrual irregularities indicates that the pain is itself a sign of ovarian dysfunction. This syndrome of ovarian pain, menstrual aberrations and other signs of ovarian failure, such as hot flushes, occurs in all ages of reproductive life. The more frequent occurrence of pain on the right side in these cases in addition to other evidence suggests that the right ovary is the more active. Observations on women from whom ovarian tissue has been removed and the known effects of partial castration in animals demonstrate the importance of an adequate mass of ovarian tissue for normal function and the urgent need for conserving ovarian tissue in women. If one ovary is removed because of pain, signs of ovarian insufficiency and pain in the remaining ovary may be expected. The beneficial effect of therapy with estrogen, including alleviation of cyclic intermenstrual pain without the prevention of ovulation, suggests that the importance of the mass of ovarian tissue lies in its production of estrogen

Endometriosis as a Cause of Intestinal Obstruction.—McGuff and his associates report that the files of the Mayo Clinic between 1920 and 1946 contain records of 48 cases in which the diagnosis of " endometriosis of the bowel " had been made by a pathologist In 16 of these 48 cases pathologic material had been removed in an effort to alleviate clinical symptoms and signs of intestinal obstruction caused by cicatrizing endometriosis. The present study concerns these 16 cases. To make the diagnosis of endometriosis as a cause of intestinal obstruction, the possibility of its occurrence should be kept in mind in every case of intestinal obstruction in which the patient is a woman from 30 to 50 years of age Acquired dysmenorrhea, menstrual periodicity of symptoms, sterility, rectal or pelvic pain, absence of loss of weight, the presence of associated uterine fibroids or ovarian cysts and a long history of intestinal symptoms which suggest progressive intestinal obstruction with frequent exacerbations at menstruation are most important in the diagnosis of this condition. Severe constipation, lower abdominal pain and distention are almost always present. If the obstruction is ileal vomiting is almost always present, but if the obstruction is colonic obstipation is more often present. An accurate preoperative diagnosis of intestinal obstruction caused by endometriosis can usually be made on the basis of the clinical history, digital examination, sigmoidoscopic examination and interpretation of the roentgenogram of the colon and the terminal portion of the ileum. The finding of a firm tumor in the rectovaginal septum or of tender palpable nodules plus the palpation of uterine fibroids and bilateral ovarian cysts is suggestive of endometriosis as the cause when intestinal obstruction is present. Sigmoidoscopic examination, with the presence of an extrarectal mass and an intact puckered mucosa, and a roentgenogram of the colon, with the presence of a long, inconstant filling defect with sharp regular borders and an intact mucosa, are the two most valuable adjuncts to diagnosis when the lesion is in the lower bowel. The treatment of intestinal obstruction caused by endometriosis is surgical. A preoperative diagnosis of endometriosis as a cause of colonic obstruction will obviate the necessity for resection of the bowel. In most instances surgical treatment will consist of bilateral oophorectomy or of panhysterectomy with or without temporary colostomy. The procedure of choice in obstruction of the ileum caused by endometriosis is ileal resection with or without preliminary enterostomy and with or without panhysterectomy as indicated by the presence of associated pelvic pathologic lesions. A plea is made for biopsy, frozen section and pathologic confirmation of the clinical diagnosis in all cases of endometrioma obstructing the bowel, as carcinoma can be positively excluded only by this method.

Endocholedochal Sphincterotomy in Recurrent Pancreatitis.—Doubilet and Mulholland believe that endocholedochal sphincterotomy should be the definite surgical procedure in the treatment of recurrent acute pancreatitis if reflux of bile into the pancreas through a common biliary pancreatic passageway can be demonstrated.

Actinomycosis of Brain.—Lewin and Morgan present clinical observations and necropsy observation on a man aged 31. The chronicity of the lesion suggests that the infection was actinomycotic from the outset. After infection of the basisphenoid bone, spread occurred to the soft tissues around the sella turcica, with involvement of the right cavernous sinus, progressive thrombosis along the superior petrosal and right lateral sinuses, and recurrent metastatic abscesses of the lungs. Infection of the meninges resulted in a subdural empyema and subpial abscess. The congenital cysts of the lungs and the amebic dysentery were coincidental lesions. Three previous cases of sphenoid osteomyelitis have been recorded, and 6 necropsy reports describing involvement of the intracranial venous sinuses in actinomycosis of the nervous system were found in the literature. The ways in which actinomycosis may spread intracranially are summarized. Over the last ten years, reports of 12 further cases have been found; they are included in the authors' summary of the modes of invasion of the nervous system by the fungus. This may occur by one of three routes. With increasing knowledge of the disease it is apparent that several of the so-called primary cases hitherto reported were secondary to foci elsewhere in the body, the original lesion healing completely or being discoverable only after diligent search. Although some authors deny that the infection can ever be primary in the nervous system, there is a small group of cases which can be classified as such.

*Suprarenal Hemorrhage and Pregnancy. C. W. F. Burnett. -p. 249.

Adrenal Hemorrhage and Pregnancy.—Burnett says that previous reports on massive adrenal hemorrhage indicate that it is usually associated with one of the following four different states: (1) involution of the gland subsequent to pregnancy or following destruction by neoplastic invasion; (2) vascular damage by toxemia, trauma, septicemia or arteriosclerosis; (3) hypertension, or (4) generalized hemorrhagic tendency. Though the evidence for most of these causes is now fairly conclusive, the suggestion that massive adrenal hemorrhage is associated with puerperal involution of these glands needs much more confirmation than is provided by the only 3 cases of adrenal hemorrhage in association with pregnancy that have as yet been reported. The author reports the case of a woman, aged 33, who was hospitalized with a threatened abortion when she was two months pregnant. After rest and sedation, progesterone and vitamin E, the bleeding stopped and the pregnancy was conserved. A month later she was hospitalized in a state of collapse and pulseless. She spoke with difficulty but said that two hours before admission she had miscarried and subsequently had felt " very ill." In spite of continuous inhalation of oxygen she became cyanosed and died twenty minutes after admission. Necropsy disclosed an adrenal hemorrhage. The author considers it impossible that such a rapid termination could be induced by physiologic involutional changes in the adrenals; it is more conceivable that the adrenal hemorrhages were responsible for the abortion. Since abortion had previously threatened, and since the patient had had three other abortions of unknown cause, there may have existed in her case an abnormal hormonal reaction to pregnancy, involving the adrenal glands. The previously reported 3 cases of adrenal hemorrhages associated with pregnancy are reviewed. It is doubtful whether puerperal or neonatal involution of the adrenals plays any part in the causation of massive adrenal hemorrhage.

Risks of Surgery in Aged. J. W. S. Laidley. -p. 136.
Risks Associated with Anesthesia of Aged. P. L. Jobson. -p. 139.

Fibrocystic Disease of Pancreas.—Pitt describes observations on 14 cases in which fibrocystic disease of the pancreas had been definitely established. In 6 additional cases the data were incomplete. This total of 20 cases was observed in two years. Of the 14 reported cases, 9 have terminated fatally. The survival of the other 5 may have been due to early diagnosis and suitable treatment. The primary deficiency is in pancreatic external secretion; secondary deficiencies of calories, protein and protein derivatives and vitamin A arise from this. It is suggested that not only does the essential metabolic difference between celiac disease and fibrocystic disease lie in protein metabolism but protein metabolism holds the key to the hepatic disorder and possibly to the pulmonary disorder. In the treatment the deficiencies must be made good. A high caloric, protein-rich and restricted fat diet must be planned. Added casein and egg are recommended as sources of protein. Evidence is produced to justify the use of pancreatin. Vitamin A may be supplied by injection. When the disease is controlled oral administration may prove adequate. Other vitamins are given by mouth. Penicillin and sulfonamide therapy is used for the recurrent pulmonary infections, from which every effort should be made to protect the child.

•Pancreatoduodenectomy for Cancer of Head of Pancreas; Recovery. P. Mallet-Guy, R. Koppes, J. Sermonard and Miss M. Rademaker. -p. 51.

Total Gastrectomy.—Vernejoul reports 39 total gastrectomies in 14 women and 25 men between the ages of 40 and 63 years. Thirty of the patients had cancer of the stomach, 4 had juxtacardiac ulcers and 5 had peptic ulcers after partial gastrectomy. Ten of the patients who submitted to surgical operation died; 9 of these had cancer and 1 had a juxtacardiac ulcer. Six of the 29 patients who survived the operation had recurrences or metastases; 1 patient was lost sight of, 10 have been operated on for less than one year The condition of the remaining 12 patients is highly satisfactory, 1 of them was operated on for cancer nine years ago and has gained 6 Kg. Juxtacardiac and peptic ulcer may present debatable indications for total gastrectomy, and vagotomy (Dragstedt's operation) may be preferred. Thus cancer of the stomach remains the main indication for total gastrectomy A study of the immediate postoperative results and of the recurrences and metastases will be an aid in answering the question of whether total gastrectomy should be limited to diffuse tumors, for which this operation is indispensable, or should be likewise performed in cases of localized tumors in the prepyloric area.

Pancreatoduodenectomy for Cancer.—Mallet-Guy and his co-workers report 1 case of cancer of the head of the pancreas in a woman aged 42. The patient had icterus of three months' duration. A large deformity of the duodenal bulb was demonstrated on roentgenologic examination. Cholecystogastrostomy and gastroenterostomy were performed in the first stage Twenty-one days later removal of the head of the pancreas was performed simultaneously with that of the inferior portion of the duodenum exactly at the duodenojejunal junction Intervention was terminated by an anastomosis of the pancreatic stump to the second jejunal loop by using Cattell's technic Healing occurred by first intention and recovery was uneventful

Penicillin for Icterus Associated with Syphilis.—Robert reports 3 cases of icterus associated with syphilis in 2 men aged 20 and 32 and in a woman aged 25. The first patient presented syphilitic icterus occurring simultaneously with syphilitic roseola and palmoplantar syphilids. The jaundice was associated with hepatosplenomegaly. The sedimantation rate was increased. Twenty thousand units of penicillin was administered every three hours for seven and a half days for a total dose of 1,200,000 units. The icterus as well as the manifestations of early secondary syphilis subsided completely within nine days. The icterus in the second patient occurred twenty-four hours after the initiation of the specific treatment with neoarsphenamine for flat condylomas, palmar syphilids and mucous plaques of secondary syphilis. The jaundice was severe but was not associated with hepatosplenomegaly. Twenty thousand units of penicillin was administered every three hours for seven and a half days. The icterus disappeared within eight days after treatment with penicillin was terminated. The rapid effect of the penicillin on the icterus suggests the presence of a hepato-Herxheimer reaction rather than a toxic arsenical lesion. In the third case the icterus occurred immediately after the first course of treatment for primary syphilis with neoarsphenamine combined with a bismuth compound was terminated. The icterus in this case is considered as being due to the neoarsphenamine and the alcoholic excesses of the patient. Penicillin, 20,000 units, was administered every three hours for seven and a half days, but the icterus disappeared only one month after the penicillin treatment was terminated. Three cases are not sufficient to solve the difficult problem of pathogenesis and differential diagnosis of icterus occurring in the course of syphilis and its treatment, but the possibility is suggested of considering the penicillin therapy as a diagnostic measure *ex juvantibus*.

Penicillin in Interstitial Polymyositis.—Por and Friedmann report 1 case of acute eosinophilic interstitial polymyositis (Wagner) in a farm woman aged 42 with acute swelling of the muscles of the extremities and of the trunk associated with pain, disturbance of general condition and rise of temperature. Penicillin treatment was instituted on the twenty-first day of the disease. Fifteen thousand units of the drug was administered every three hours for a total dose of 1,500,000 units. Temperature was restored to normal within six days. Swelling subsided gradually and the general condition was improved. The patient was discharged from the hospital three weeks after the initiation of the penicillin treatment. She was able to resume her work in the house and in the field. This is the first case of interstitial polymyositis in which complete recovery resulted from penicillin therapy.

Goiter in Newborn Infants.—To prevent the occurrence of goiter in newborn infants, Wespi-Eggenberger gave 132 pregnant women 150 to 200 micrograms iodine daily for at least the last four weeks of pregnancy This prophylaxis was carried out either by the administration of 3 drops of a 1 per cent solution of potassium iodide daily or of iodized sodium chloride (20 mg. potassium iodide to 1 Kg. sodium chloride). Eight hundred and fifty-six women in whom this prophylaxis has not been carried out served as controls. One hundred and twenty-one (91.6 per cent) newborn infants whose mothers had received the prophylactic treatment presented a normal thyroid gland, 10 (7.6 per cent) presented a small goiter and only 1 (0.8 per cent) had a medium-sized goiter. Five hundred and forty-one (63.2 per cent) newborn infants whose mothers did not receive the treatment had normal thyroid glands, 274 (32 per cent) had a small goiter, 31 (3.6 per cent) had a medium-sized goiter and 10 (1.2 per cent) had a large goiter. This comparative study, made at the hospital in Frauenfeld in the Canton of Thurgau, revealed that the incidence of goiter in the newborn infants had been reduced from 36.8 per cent to 8.4 per cent and that goiters of large and medium size had disappeared almost completely. These results are in accordance with those obtained by similar studies in the Cantons of Zurich and Appenzell. The goiter problem is one of iodine dosage The goiter itself is a sequela of iodine deficiency

Book Notices

Planning for the Care of the Chronically Ill in New York State—Some Medical-Social and Institutional Aspects. New York State Commission to Formulate a Long Range Health Program also Known as New York State Health Preparedness Commission. State of New York Legislative Document (1946) No. 66A. Paper. Pp. 131, with 1 illustration. Joint Hospital Survey & Planning Commission. Gov. A. E. Smith State Office Bldg., Albany, N. Y., 1947.

This study is further evidence of the excellent work being done by the New York State Commission to Formulate a Long Range Health Program. The commission has released other studies in the health field which were equally excellent. In this study special attention is given to the care of the chronically ill between hospital and home, to the points of view of local public welfare and the hospital on the problem of the chronically ill, and to the place of nursing homes in the care of the chronically ill. The data of the commission are presented with a clearness unusual in such a difficult subject. Maps are utilized to show the pattern of the observations throughout the state. Forty-eight tables are included to give readers the many details necessary for an understanding of the commission's conclusions. To allow for comparison and for a broader vision in planning, the commission has included a fairly detailed summary of the programs for the chronically ill in six other states, together with the details of licensing procedures for nursing homes in the six states. For those interested in the care of chronically ill this study is essential reading. Similar studies in every state would place the solution within reasonable possibility.

Out of This World: Anesthetics and What They Do to You. By Sylvan M. Shane, M.D., Director of Anesthesiology, South Baltimore General Hospital, Baltimore. Cloth. Price, $2. Pp. 111, with 4 illustrations. Creative Age Press, Inc., 11 E. 44th St., New York 17, 1947.

This book is one which could well be read by every person who anticipates having an operation or who has a friend or relative about whom he is concerned. The book easily accomplishes its purpose of dispelling fears associated with anesthesia as well as giving a concise clear summary of the anesthetics in popular use today. The style of the book is novel, having accurate information presented in a very entertaining and often humorous manner.

The sensations of the patient before going to sleep are colorfully described. The advantages of ether anesthesia over other general anesthetics used, and what these are, are clearly given, and the use of local anesthesia is discussed both as to its limitations and indications. Each chapter is cleverly introduced and arouses an interest in the contents which follow, especially on the subject of childbirth. There is an excellent description of the events which occur in the delivery room, and some of the recent developments in local anesthesia during labor are presented. The latest type of anesthesia—the so-called saddle block or low spinal—is omitted. The use of hypnotism in obstetrics is mentioned, and its further use in surgery and other fields is implied. One of the most delightful portions of the book is the physiology and anatomy in relationship to the mechanism of the action of anesthetic agents. In the closing pages the author gives a fascinating preface to a thrilling story which he relates—the story of the discovery of anesthesia.

So Youth May Know: Sex Education for Youth. By Roy E. Dickerson. Forword by Percy R. Hayward, Editor of International Journal of Religious Education. New edition. Fabrikoid. Price, $2.50. Pp. 259, with 26 illustrations. Association Press, 347 Madison Ave., New York 17, 1948.

This book has gone through twelve printings. New materials have been added and revisions made in the light of scientific progress. An attempt is made to provide young people with accurate scientific information to replace misconceptions.

The book presents information pertinent to the real life experiences of teen-agers in clear, understandable language. The role of clean living in the development of an attractive personality is stressed, and self control given a positive emphasis as a means of attaining one's goal and ideals.

The first part of the text deals with human reproduction and the meaning of sex, and seeks to give youth the benefit of the newer interesting and important scientific discoveries in the field. The straightforward approach to problems of friendship, love, abstinence, promiscuity and petting in the second section is especially noteworthy. Part three is given over to methods of achieving self control, while the next section is devoted to courtship, engagement and marriage. The last part of the book, setting forth new ideals of sex chivalry, should be a stimulus to clean living for our young people. A rather detailed appendix, covering the mechanism of sex, prostitution, venereal diseases and masturbation, provides specific information to youth on these problems as they relate to modern society.

The book was first written for young men in their late teens and early twenties, but newer attitudes toward frank treatment of sex matters would suggest that many boys can read the material with profit at 14 or 15 today.

Life: Its Nature and Origin. By Jerome Alexander. Cloth. Price, $5. Pp. 291, with 31 illustrations. Reinhold Publishing Corporation, 330 W. 42d St., New York 18, 1948.

Jerome Alexander, the distinguished colloid chemist, presents his stimulating theory of the origin and nature of life in this refreshing book, which is packed with erudition. Mr. Alexander's knowledge of chemistry is profound, and yet he has had the time and interest to acquire a wealth of information about biology and medicine; these combine to furnish a rational account of many processes occurring in the living cell which because of the author's chemical point of view will be read with profit by all those seeking a deeper insight into the nature of living things and a more fundamental understanding of medicine.

Mr. Alexander begins by stating that life is an accomplished fact, a practical going concern and not a figment of someone's imagination—there must be some mechanism through which it got started. The most reasonable view is that life began with the chance formation of a self-reproducing unit of molecular or near molecular complexity. Life depends on a great variety of ordered chemical reactions which are limited in space, mass and time. The evidence presented indicates that "many if not all the basic material facts of life are understandable on catalytic principles including selective absorption and differential diffusion. But the mental and spiritual phenomena which emerge and which are just as real as the material ones, are as inscrutable as ever."

Catalysts promote syntheses or degradations of matter and they function "like a duly qualified judge who may wed or divorce couples who come within his jurisdiction and remain there long enough for the operation." Catalysts (enzymes) are essential to life and must reproduce themselves? The formation of new catalysts is considered comprehensively from the standpoints of immunology, genetics, embryology, differentiation and morphogenesis—catalysis is the basic mechanism of all of these fields. Also many, if not all, drugs which are effective in small amounts operate on specific enzyme systems. For the reproduction of catalysts (autocatalysis) Mr. Alexander favors the template theory in common with many of our most distinguished contemporary thinkers. This process may be likened to silver foil that is pressed firmly against a coin; on the foil surface nearest the coin it will develop a negative image of the coin detail, while it will duplicate the coin on the surface of the foil farther away.

Jerome Alexander's opinions must be considered seriously, since the scientific evidence is sound. The present work is a profound study, but it is written with much simplicity and charm, and it abounds both with elegant phrases and with wit. Many readers will derive pleasure and profit from it.

Opiate Addiction. By Alfred R. Lindesmith, Associate Professor of Sociology, Indiana University, Bloomington, Indiana. Cloth. Price, $3. Pp. 238. Principia Press, Inc., Bloomington, Indiana, 1947.

This book is based on information which the author obtained by interviewing 60 to 70 morphine addicts in the course of a sociologic study of drug addiction which was carried out fifteen years ago. The writer has been publishing articles on drug addiction based on this same material since that time. A perusal of the book forces one to the conclusion that the author has, in large part, accepted the views of the confirmed addicts who formed his case material as being the correct ones concerning addiction.

The central theme of the book is that a person is not an addict until he has experienced the distress of withdrawal of an opiate, has recognized the distress as being due to the lack of the drug, has used the drug to relieve the symptoms of abstinence and has been informed of the name of the drug. As a result of this experience, the person develops a number of characteristic attitudes, including a tendency to use the drug to alleviate not only the distress of withdrawal but any form of distress. This hypothesis does not explain all the phenomena of addiction. It does not account for the fact that most persons who become addicted to morphine in the United States begin the use of the drug with full knowledge that if they continue to take it over any long period of time they will become addicted. Despite this knowledge, which they usually have because of their contacts with habituated addicts, such persons progressively increase the number of doses and the amount of the drug until they become addicted. Although the author states that the effects of the drug may be pleasurable to certain persons and that "a sensitive man of certain neurotic ailments may be tremendously impressed with the soothing qualities of the drug, and by contrast with his usual state of mind, may feel intense pleasure," he tends to minimize the importance of the pleasurable effects of morphine in the genesis of addiction.

The author believes that the importance of emotional and personality disorders in the etiology of addiction has not been proved. He complains that persons who have attributed addiction to personality difficulties did not use control groups. He implies that a sample of the ordinary nonaddict population would show as great an incidence of marked psychopathic and psychoneurotic traits as occurs among drug addicts.

Lindesmith doubts that psychiatric treatment is of any value in the treatment of drug addiction; he believes that the "cure is up to the addict himself." The latter view probably arises from the nature of the material on which the book was based. Most of the addicts whom the author interrogated were actively using drugs at the time of the interview, and some were paid for their cooperation. The hopeless attitude of the author regarding treatment seems to be identical with the attitude of confirmed addicts. The author has, apparently, made no effort to locate and study addicts who have received modern treatment and who have remained abstinent for many years. He would certainly not find such persons in the fringes of the underworld where he conducted his study.

The measures which the author proposes as a solution of the addiction problem in the United States are startling and dangerous. He would reinterpret the Harrison Narcotic Act so that physicians could legally prescribe drugs for the maintenance of addiction alone. The addict would then have a legitimate low cost source of supply and would not be forced to purchase his drugs in the illegal market. Although the author states that availability of drugs and contact with persons already addicted are factors which contribute greatly to the spread of addiction; he does not believe that the mechanism he proposes would tend to spread addiction. In spite of the fact that he admits that addicts will increase their dosage beyond bodily needs if the drug is available, he implies that physicians could limit the spread of addiction by limiting the amounts supplied the addict for his bodily needs. Addicts would, of course, circumvent such a system by obtaining prescriptions from many physicians and would not hesitate to supply any surplus drugs which they might have to curious thrill-seeking nonaddicts. The author believes that his plan would not increase the incidence of addiction because of the situation in England. Although physicians prescribe for addicts in England, there is less addiction in the United Kingdom than in the United States. It seems especially naive that a sociologist would assume that conditions in the United States and England are identical. Addiction to opiates was never a great problem in England, even when opiates could be obtained there without prescription, while in the United States, as the author admits, the morphine habit was spreading rapidly prior to the passage of the Harrison Narcotic Act. The author also ignores the seriousness of the narcotic situation in countries where opium is easily available.

The book cannot be recommended.

Die gynakologischen Operationen und ihre topographisch - anatomischen Grundlagen. Von Prof. Dr. med. Heinrich Martius, Direktor der Universitats-Frauenklinik Gottingen. Fifth edition. Boards. Price, 58 marks. Pp. 424, with 427 illustrations by Käthe Droysen. Georg Thieme, Diemershaldenstrasse 47, Stuttgart-O (American Zone), 1947.

This is a revised edition of a volume on gynecologic surgery which has enjoyed considerable popularity. Considering the difficulties under which German books are published, this is an excellent publication. All of the standard gynecologic procedures including their surgical anatomy are described and profusely illustrated. Many of these pictures and diagrams are in contrast colors adding to the ease of their interpretation. There are no new or spectacular additions to this text. Conspicuous by its absence is a discussion on modern anesthesia and preoperative and postoperative care of the gynecologic patient. These are fields in which the greatest progress has been made in the last decade.

A Survey of Diagnostic Agents. By T. D. Whittet, Ph.C., D.B.A., Chief Pharmacist, University College Hospital, London. Based on a Series of Articles Which Appeared in "The Pharmaceutical Journal," April-May, 1947. Published by the Pharmaceutical Society of Great Britain. Paper. Price, 2s, 6d. Pp. 32. The Pharmaceutical Press, 17 Bloomsbury Square, London, W. C. 1, England, 1947.

The contents of this little booklet have been assembled chiefly from material published in the *Pharmaceutical Journal* of Great Britain. The author states that the purpose of this book is to provide in permanent form information required by pharmacists studying for the diploma in biochemical analysis and for postexamination use when they are called on to prepare the diagnostic reagents described. In concise form many diagnostic methods now commonly used in medical practice are minutely described. The exact ingredients and the manner of performing the tests are also disclosed. Many of the procedures are among those routinely ordered by physicians for certain conditions so as to establish or confirm a diagnosis. This book, of pocket size, is suitable for rendering valuable service to the practicing physician as well as to the pharmacist. There is an index for convenience.

Reconstructive and Reparative Surgery. By Hans May, M.D., F.A.C.S., Assistant Professor of Surgery, Graduate School of Medicine, University of Pennsylvania, Philadelphia. Foreword by James Barrett Brown, M.D., F.A.C.S. Fabrikoid. Price, $15. Pp. 964, with 963 illustrations. F.A. Davis Company, 1914-1916 Cherry St., Philadelphia 3, 1947.

The author reviews the standard concepts of preoperative preparation, including the use of standard instruments and suture materials. He discusses the various types of skin graft, the historical background, subsequent development and modification of their uses. The general and local preoperative and postoperative management is covered, insuring optimum results. He then discusses the various types of free transplants and also the consideration and planning of tissue shifting and transplantation by means of the single pedicle flap, double pedicle flap and tube flaps. Wound healing and treatment of wounds, including the classification of wounds and their individual treatment in relation to time interval, is discussed according to modern concepts including chemotherapy and use of antibiotics. There is the usual historical review of evolutionary treatment of burns, classifying them into three degrees, with discussion of treatment of each. He points out the importance to lifesaving of measures to maintain the protein fluid level of the blood. In summary, the accepted treatment is: maintenance of asepsis of the denuded areas; supportive treatment as combating infection and loss of protein, and early covering of denuded areas with split grafts, particularly over movable joints. The operative correction of scars is discussed according to usual accepted methods. With regard to the cheek, temple and skull region, he points out that small defects of the face involving only skin and subcutaneous tissue can be handled by tissue-shifting operations. Large defects including skin, muscle and mucosa are to be corrected by pedicle flaps, either from adjacent or remote areas. The section on lips, chin and palate shows many variations of procedures for closing defects of the lip, but these are standard and appear in all textbooks. In the discussion of cleft lip Blarr's modified Mirault operation is illustrated, but the major portion of the illustrations on cleft lip and cleft palate are taken from G. Axhausen, even to the extent of carrying German titles. In the section on the nose and intranasal regions the author discusses defects of the columnella, tip and alar aspects and describes the usual standard operation for their correction. He also discusses the utilization of flaps from adjacent and remote parts to cover extensive defects. Subtotal and total defects of the nose are illustrated by the technic of the Indian and Italian methods. Deformities of the nose, congenital and traumatic, are described according to the technic of Joseph with little modification. Defects of eyelids, eyebrows and orbits are corrected by the standard methods previously described.

Defects of the ear, both partial and complete, are corrected by the usual methods. Deformities of the ears, such as protruding ears, large ears and cauliflower ears, are corrected by recognized technics. The osseous framework of the face as to fractures of the mandible and maxilla, the prosthetic appliances for the face and the neck, larynx and trachea are discussed in a limited way.

The section on skeletal bones and joints is superficial and does not discuss bony problems with deep enough penetration. The author's illustrated cases show consistently good results except for cosmetic correction of nasal deformities, which show improvement but do not demonstrate results that are obtained by the refinements of technic of the last ten years. This book is an adequate reference in methods and planning of reconstructive surgery.

Textbook of Human Physiology. By William F. Hamilton, Ph.D., Professor of Physiology, University of Georgia School of Medicine, Augusta. Cloth. Price, $6. Pp. 504, with 121 illustrations. F. A. Davis Co., 1914-16 Cherry St., Philadelphia 3, 1947

The organization of this text is excellent, except that an undue amount of space is devoted to special senses A unique feature is a discussion of pain and vivisection As is to be expected from this author's interests in the circulatory field, the circulation likewise receives a disproportionate amount of attention, one hundred and twenty-three pages compared to twenty-one for the digestive system, eleven for the kidney and thirteen for metabolism The endocrines are covered in twenty-one pages. Despite great personal respect for both the author's character and personality and his scientific understanding, the need for the book is not clear, despite considerable explanation in the author's preface It seems to be just another textbook suitable for an elementary medical student, but likely to be misleading to one who is not too inquiring.

Handbook of Physiology & Biochemistry. Originally "Kirke's" and Later "Halliburton's." By R.J.S. McDowall, M.D., D.Sc., Professor of Physiology, University of London, King's College London. Thirty-ninth edition. Cloth. Price, $7. Pp. 899, with 305 illustrations. The Blakiston Co., 1012 Walnut St., Philadelphia 5, 1946.

Designating this book the thirty-ninth edition is somewhat misrepresentative, as it bears no more resemblance to the original Kirke's Handbook than does an early number of the *Saturday Evening Post* to its present day namesake. The type is too small for comfortable reading. Some of the illustrations are reminiscent of the day when students entered medical school with no training in physics or chemistry and it was necessary to provide fundamental information now readily available to all students. Many of the illustrations are evidently original work of the author. The material in the text is factual and well condensed, so that the entire subject is presented in something over eight hundred pages in a manner quite as adequate as in many more voluminous tomes. The most notable exception to this is the chapter on endocrines, the entire subject being covered with twenty-five brief pages. While most of the essential details are presented, certainly there can be no question of the need for greater detail on many points. There seems to be little justification for illustrations such as figure 132 on page 325 or for the accompanying directions for making a blood count. Many procedures are employed in the laboratory which might be much more aptly discussed. The inclusion of the word biochemistry in the title is also a misnomer, because the book carries very few of the features of the textbook of biochemistry. However, it is a good textbook for medical students, and the fact that it continues to be popular under its present authorship is evidence that students find it desirable.

ADOPTING A CHILD. By Frances Lockridge. With the Assistance of Sophie van S. Theis, Secretary of the Child Placing and Adoption Agency of the State Charities Aid Association. New York. Cloth. Price, $3. Pp. 216. Greenberg: Publisher, 201 E. 57th St., New York 22, 1947.

Not often does one read a book on a subject so sentiment ridden and emotionally charged as adoption that one can wholeheartedly and without reservation recommend to parents seeking children to adopt This book achieves the unusual success of being warm and human, highly informative, accurate and balanced The author reviews the history of adoption, its recent growth and its present status The functions and point of view of adoption agencies and the "black market" in babies are discussed Sources of babies and children for adoption are described, and the procedure and purposes of good adoption practice are carefully reviewed. The volume is replete with human anecdotes effectively woven into the explanation of the book The volume closes with a list of public and private adoption agencies in the United States and Canada The publisher makes an abbreviated edition available for 25 cents.

Patología digestiva: Actualidades clínico-radiológicas y terápeuticas. Tomo II. Editado por B. Varela Fuentes, profesor de clinica de nutricion y gasteroenterologia, de la Facultad de medicion de Montevideo, Montevideo, y Alberto Munilla, director de la Escuela de dietistas, de la Facultad de medicina de Montevideo. Paper. Pp. 782, with illustrations. Espasa-Calpe Argentina S. A., Buenos Aires, 1947.

This is an ambitious work, well written, printed, illustrated and documented. Every Spanish-speaking gastroenterologist will want to have a copy on his desk. There are chapters on constipation, the radiologic study of the terminal ileum and the ileocecal sphincter, amebiasis, chronic ulcerative colitis, cholecystography, congenital malformations of the biliary tract and hydatid disease of the liver, cirrhosis of the liver in the child, obstruction of the cystic duct, a study of the metabolism of the biliary pigments, anemia with falciform red blood cells, experimental pancreatitis, alcaptonuria and two chapters on certain phases of diabetes. The treatment of chronic ulcerative colitis is that used in the United States today. In this disease penicillin appears to be of value mainly to clear up complicating inflammations. There is a curious chapter on the treatment of gastroduodenal ulcer with female sex hormones. There is a good chapter based on research as to the innervation of the digestive tract. Other unusual chapters are on intra-abdominal pressure, the innervation of the liver and the biliary tract and xanthomatosis with cirrhosis of the liver. This last appears to be a common condition in Argentina.

Congenital Malformations of the Heart. By Helen B. Taussig, M.D., Associate Professor of Pediatrics, Johns Hopkins University School of Medicine, Baltimore. Cloth. Price, $10. Pp. 618, with 177 illustrations. The Commonwealth Fund, 41 E. Fifty-Seventh St., New York 22; Oxford University Press, Amen House, Warwick Square London, E. C. 4, England, 1947.

This book on congenital malformations of the heart must be on the desk of every cardiologist and physician interested in congenital heart disease. Even those who occasionally see a patient with congenital heart disease will enjoy reading this book and will be aided in making a correct diagnosis. The book is well planned, clearly and concisely written. Each type of congenital malformation of the heart is dealt with similarly according to a definite pattern. This plan makes the book an excellent reference work in which one can find promptly what is being sought. Students and practicing physicians enjoy reading a book in which facts and observations are arranged in an orderly manner on a simple, well formed trellis where they can be seen.

The reading matter is well clarified by illustrations which truly illustrate. Reproductions of roentgenograms are good, and the line drawings indicating what is to be seen in these roentgenologic pictures are helpful. Schematic colored plates showing the course of the circulation of the heart give the reader a clear mental image of the basic pathologic condition. Again, this book on congenital malformations of the heart is a "must" for every clinician who is interested in congenital heart disease. In the foreword Dr. E. A. Park makes this pointed comment: "Dr. Helen B. Taussig has done for the clinician what Maude Abbot did for the pathologist; namely, made the malformations of the heart understandable and accessible."

Chemical and Physical Investigations on Dairy Products. By H. Eilers, R. N. J. Saal, and M. van der Waarden. Executed by Order of the General Netherlands Dairy Union (Coöperative Dairies). Monographs on the Progress of Research in Holland During the War, No. 12. Paper. Price, $4. Pp. 215, with 51 illustrations. Elsevier Publishing Company, Inc., 215 Fourth Ave., New York 3, 1947.

This volume contains three papers on subjects connected with the chemistry of dairy products and is one of a series of monographs on the progress of research in Holland during the war. The first paper, by H. Eilers, deals with the colloid chemistry of skim milk and covers the calcium-caseinate-phosphate phase of milk, the proteins denaturable by heat and the behavior of skim milk on concentration. The second paper, by Saal and Heukelom, covers work on the oxidation-reduction potential of milk and of butter-plasma. The last paper, by van der Waarden, gives researches on the chemical processes underlying the deterioration of the flavor of butter in cold storage. In all cases the authors present an accurate review of the older literature as well as the recent work which they have conducted. Since much recent work is available on the amino acid content of casein, significant changes can now be made in the table opposite page 6. This monograph should be valuable to any one dealing with the processing of dairy products.

The 1947 Year Book of General Medicine. Edited by George F. Dick, M.D., and others. Fabrikoid. Price, $3.75. Pp. 734, with 113 illustrations. The Year Book Publishers, Inc., 304 S. Dearborn St., Chicago 4, 1947.

This volume is well up to the standard of previous contributions now so well known to the medical profession. The numerous comments by the editors help to make much more valuable the capable abstracts.

Ulcer: The Primary Cause of Gastric and Duodenal Ulcer: Diagnosis, Medical and Surgical Treatment, Prevention. By Donald Cook, B.A., M.D. Cloth. Price $5. Pp. 192, with 27 illustrations. Medical Center Foundation and Fund, 30 N. Michigan Ave., Chicago 2, 1946.

The author has written in an interesting manner the medical facts and theories surrounding the most widely discussed topic—peptic ulcer. He mentions all the common theories of ulcer causation and notes the factors that are not explained in each of these theories. Then he speaks of the "primary cause" of ulcer, whether gastric or duodenal, which is his contribution to the subject. It is based on ischemia and anemia of the stomach mucosa and wall, due to pressure against the stomach by the posterior wall of the liver and behind by the spinal vertebral bodies, the crura of the diaphragm and the firm prevertebral tissue. He pays especial attention to the length of time the ulcer-bearing area of the stomach is held in the angle of the hepatovertebral notch and the severity of the pressure and the anemia which results. This lowering of tissue resistance predisposes to ulcer formation. He then ingeniously fits all the theories into his "primary cause" and works out treatments in the same way, fitting in the various factors of treatments, complications and surgery. He quotes at length from the work of Sippy, which he describes as "a classic" which made ulcer a "medical condition" and perfected "a treatment" to which little has been added in the last thirty years. He has added a concept of the pathologic condition which fits into the ideas of decreased resistance of the stomach wall, that allows the digestive action of the secretions of the stomach, hydrochloric acid, activating pepsin, to cause peptic ulcer. Also, he explains the good effects of frequent feeding and use of alkali in medical management, largely on the basis of drawing the ulcer-bearing area of th stomach away from the hepatovertebral notch rather than on the ground of acid control.

Rehabilitation of the Physically Handicapped. By Henry H. Kessler, M.D., Ph.D. Cloth Price, $3.50. Pp. 274. Columbia University Press, 2960 Broadway, New York 27, 1947.

In the expanding field of rehabilitation and services to the handicapped, there has long been needed a single, comprehensive volume such as this, to give the physician, nurse, social worker, therapeutist rehabilitation counselor, placement specialist and personnel administrator an introduction to and general survey of the modern concepts of rehabilitation. Long a leader in the field of rehabilitation, and currently president of the National Council on Rehabilitation, Dr. Kessler has had both the professional training and the experience necessary to present and interpret the growing rehabilitation movement. After completing his medical education he received both the M.A. and the Ph.D. degree in the social sciences. In 1919 he became assistant director, later medical director, of the New Jersey Rehabilitation Clinic, the first such government service in the United States. A pioneer in the cineplasty technic of amputation, Dr. Kessler, as a captain, developed the Navy's outstanding rehabilitation program for amputees at Mare Island, Calif. Since the war he has served as a consultant to the Office of Vocational Rehabilitation.

In his analysis of the present status of rehabilitation in the United States, Dr. Kessler repeatedly calls attention to the great gap between the number of physically handicapped persons in this country and the appalling lack of facilities and trained personnel to give them the services which they need. He points out, however, that great progress has been made in the past twenty-five years, particularly during World War II, in the recognition that the social, economic and personal factors are equally as important in rehabilitation as the physical. Much of this improved status of the disabled he attributes to the demonstration by physically handicapped persons during World War II that they are efficient, reliable and valuable workmen when selectively placed in jobs commensurate with their physical capacities, and to the growing professional and public interest in rehabilitation springing from the successful programs of the military services during that period. The factual material which Dr. Kessler presents has been, until now, scattered in dozens of professional journals of a score of various professional fields. Its synthesis into one volume, together with his experienced analysis and stimulating style, makes this an informative sourcebook for all concerned with this major medical, social and economic problem.

Sex in Our Changing World. By John McPartland. Cloth. Price, $2.75. Pp. 280. Rinehart & Co., 232 Madison Ave, New York 16, 1947.

The author's thesis holds that millions of persons look on sex as a form of diversion and not as the basis of a permanent, lastingly satisfactory relationship. His contribution to the literature is a mixture of scientific comment and crude observation. The volume goes somewhat beyond the borders of popularization of sex knowledge. After reading the author's chapters on homosexual persons and sex crimes, one might recommend that the author read over his own chapter on boundaries of decency.

Blood Pressure and Its Disorders Including Angina Pectoris By John Plesch, M.D., L R.C.P.&S. Second edition. Cloth. Price, $6. Pp 307 with 125 illustrations. Williams & Wilkins Co., Mount Royal and Guilford Aves, Baltimore 2, 1947.

The first edition was unenthusiastically reviewed in THE JOURNAL, Dec. 23, 1944. One hundred and fifty-eight pages and sixty-four illustrations have been added to the second edition. Like the first, it deals principally with tonoscillography. As such it seems adequate in technical detail and may be of value to students of this method. As a clinical text on circulatory disease it is unpardonable. To describe the syndrome of malignant hypertension as "capillaritis generalis" and to illustrate it from the detailed case history of Colonel N , noting through several pages, such irrelevancies as his blood count, the straw color of his urine and the mucoid cloud it formed on standing; to make a plate of his altogether undistinguished electrocardiogram (leads 1, 2 and 3), indicating it as typical of the disease, and then to ascribe his illness to the "festering of a war wound" is gibberish. Postprandial angina pectoris does not respond to a kosher diet, nor is cupping recognized as an acceptable alternative. Angina with persistent discomfort is hardly to be treated three times a day by a powder which combines theobromine, "luminal" (phenobarbital) and 1/20 grain (3 mg.) "dilaudid" (dihydromorphinone), even for six weeks. The body fluids do not contain 0.85 per cent sodium chloride (NACl). The author's low sodium diet "still contains so much salt that the daily output of NaCl in the urine is about 1 per cent." It is amazing that the publisher should adorn with elegant format and honored name this ill digested mass of fat, fancy and foolishness. Caveat emptor.

Andreas Vesalius Bruxellensis: The Bloodletting Letter of 1539: An Annotated Translation and Study of the Evolution of Vesalius's Scientific Development. By John B. deC. M. Saunders, F.R.C.S., and Charles Donald O'Malley. Cloth. Price, $5. Pp. 94. Henry Schuman, 20 E. 70th St., New York 21, [n. d.]

For the medical historian any writing of Vesalius is significant. This discussion of a letter on bloodletting, published in 1539, is beautifully presented in a work with numerous and competent annotations. It affords an insight not only into the knowledge of anatomy of that day but also into many other other aspects of scientific work.

Modern Dermatology and Syphilology. By S. William Becker, M.D., Clinical Professor of Dermatology, University of Chicago, Chicago, and Maximilian E. Obermayer, M.D., Clinical Professor and Chairman of the Department of Dermatology, University of Southern California, Los Angeles. Second edition. Fabrikoid. Price, $18. Pp. 1017, with 498 illustrations. J. B. Lippincott Co., 227 S. 6th St., Philadelphia 5, 1947.

The new edition of this contribution to textbooks in the field of dermatology brings up-to-date studies in many fields of dermatology. It adds the advances on tropical medicine made during World War II, revises the section on syphilis by considering the therapeutic uses of penicillin and makes its nomenclature conform to the Standard Nomenclature of Disease. The quality of the printing, the paper and the illustrations make this book especially valuable for the general practitioner and student.

Textbook of Endocrinology. By Hans Selye, M.D., Ph.D., D.Sc., Professor and Director of the Institut de médecine et de chirurgie experimentales, Université de Montréal. With a preface by Professor Bernardo A. Houssay. Cloth. Price, $12.80. Pp. 914, with illustrations. Acta Endocrinologica, Universite de Montréal, Montreal, Canada 1947.

In the introduction, Dr. Bernardo Houssay says, "This book represents a critical and concise, orderly presentation of what is most important in the immense collection of facts of modern endocrinology." Each of the chapters has been surveyed by recognized experts in the special field concerned, and chapters are devoted to each of the important glands and glandular systems of the body. A final chapter entitled "Correlations" draws together the interrelationships that govern the sexual cycle, pregnancy, lactation and adaptation. The book is excellently printed on good paper, and the illustrations are among the finest available in any of the books devoted to such subjects. The volume avoids the difficulties associated with the use of other textbooks in the field, of too much pro and con discussion, by a didacticism which represents the voice of authority. Nevertheless, the author does not hesitate to indicate the Lack of positive information where it is not yet available. The index offers an unusual contribution in its indication of target organs and the influences that act on them.

A Text-Book of Mental Deficiency (Amentia). By A. F. Tredgold, M.D., F.R.C.P., F.R.S., Consulting Physician to University College Hospital, London, England. Seventh edition. Cloth. Price, $8.50. Pp. 534, with illustrations. Williams & Wilkins Co., Mount Royal and Guilford Aves., Baltimore 2, 1947.

This book has the standard British approach to the problem of the mentally defective, and the legal aspects are those that prevail in Great Britain. There are, nevertheless, reports of writings in the American field, but the statistics cited are for the most part those previous to 1917 except one article published in 1933. There is an almost complete disregard of modern dynamic psychology. One is startled by the author's suggestion that the prostitute who practices her profession "in a decent respectable manner" is not vicious, but if she openly and persistently flaunts herself, she is Among the most interesting chapters is one called "Idiot Savants."

Temas de cancerilogia y radioterapia. Conferencias dictadas en el curso libre de cancerologia del ano de 1945, bajo la direccion de los profesores Cesar A. Pantoja, director del Instituto de radium, Universidad Nacional de Colombia, y Alfonso Esguerra Gomez, profesor titular de cancerologia. Recopilacion, redaccion y edicion de Luis Maria Borrero H. Revision literaria del Dr. Nicolas Bayona Posada, relator del Instituto. Campana colombiana contra el cancer. Paper. Pp. 675, with illustrations. Editorial Minerva, Ltda., Bogota, 1946.

This volume is a compilation of the lectures given in the National Radium Institute of Colombia, by the staff of the Institute and professors of the National University. The first part of the book is devoted to the social, laboratory and clinical aspects of cancer. Following this there is a chapter on the roentgen diagnosis of this special field. The second part is devoted to the physics of curietherapy and roentgenotherapy, which forms the main body of the book, and is illustrated by numerous diagrams. There is a short chapter on surgery and biology of cancer. The format and general appearance of the book are excellent.

Music and Medicine. Edited by Dorothy M. Schullian and Max Schoen. Cloth. Price, $6.50. Pp. 499, with illustrations. Henry Schuman, Inc., 20 E. 70th St., New York 21, 1948.

For many years Col Fielding H. Garrison was interested in the relation of music to medicine and published earlier one of the best essays on the subject, entitled "Medical Men Who Have Loved Music." That essay appears complete in the present symposium together with contributions on the subject by other interested writers. There are such chapters as musical therapy, music and hospitals, emotional expression in music and the occupational diseases of musicians. Thus far there has been no other comprehensive scientific book available in this field, although there has been a mass of incompetent unscientific writing. This book brings together the state of existing knowledge in a field in which esthetics and science draw closely together.

Dermatologie fur Augenärtze. Von Walther Schonfeld, Prof. Dr. med. an der Universitat Heidelberg. Boards. Price, 24 marks. Pp. 109, with 92 illustrations. Georg Thieme, Diemershaldenstrasse 47, Stuttgart-O (American Zone), 1947.

In his preface the author states that this is not a substitute for a text book on dermatology. he divides his material into diathesis, by which he means hereditary cinstitutional disease, and skin diseases. Under the former, he discusses seborrheic dermatitis, exudative diathesis and allergic disease. The skin diseases are discussed under (1) diseases of unknown etiology, diseases of known infectious etiology and virus infections: (2) diseases caused by light and heat, toxicity, avitaminosis, sarcoid, congenital and hereditary conditions, cancerous and noncancerous tumors, and (3) diseases of the cutaneous appendages such as hair, skin glands and pigment. Descriptions of various entities are short but adequate. The therapy of most conditions is described in only a line or two. The book is a good summary of cutaneous lesions seen by the ophthalmologist.

The Case of Rudolf Hess: A Problem in Diagnosis and Forensic Psychiatry. By Physicians in the Services Who Have Been Concerned with Him from 1941 to 1946. Edited by J. R. Rees. Cloth. Price, $3. Pp 224 W. W. Norton & Co., Inc., 101 Fifth Ave., New York 3, 1948.

The eight British and American psychiatrists who studied Rudolf Hess from 1941 to 1946 make available here their observations of this extraordinary character. Obviously the egomaniac was happy to know that he was of such importance, but where he now is, pleasure in this volume is probably exceedingly slight. In his letter that accompanies the book, written on Sept. 17, 1946, he takes it for granted that the experts who examined him did so by compulsion and that their attitude toward him was a crime. The experts incline to the conclusion that Rudolf Hess was a case of schizophrenia of a paranoid type Yet they recognize that a study of the structure and dynamics of his total personality made difficult any simple label. The whole story of Hess is told in this quotation: "...he appears as a self-centered, shy, shut-in, authistic personality, submissive but antagonistic to his father in early life, more devoted to his mother and what she stood for, suffering from guilt and an unsettled employment problem, given to an unstable alternation between heroic aggressive and doggedly-industrious, submissive patterns of living, caught in the swirling political currents of his country, with whose fate he becomes emotionally identified and whose extreme forms of irrationalities he is driven to adopt by his craving for devotion and fantasies of glory. He basks briefly but uneasily in the early sunshine of Nazi success but his haunting sense of inadequacy and inner conflict destroy his influence in a position of power far beyond his capacity—perhaps a little to his credit in the setting in which he was expected to live his life."

The 1947 Year Book of General Therapeutics. Edited by Oscar W. Bethea Ph.M., M D. F.A C.P. Cloth. Price, $3.75. Pp. 455; with 33 illustrations The Year Book Publishers, Inc., 304 S Dearborn St., Chicago 4, 1947.

This book summarizes much that is new in therapeutics in a way which enables the reader to get his information promptly. Due consideration is also given to new diagnostic tests and devices for therapy. The sulfonamide drugs and the antibiotics are exhaustively reviewed. There are good summaries as to the presently accepted indications, contraindications, complications and modes of therapy of these agents. The parasitic diseases have also been given an extensive discussion, particularly the protean manifestations of amebiasis Two new drugs—"diramin" (an aqueous solution of the products resulting from the reaction between antimony catechol and triisopropanolamine in the presence of propylene glycol) and "melarsen" (a pentavalent arsenic preparation)—are here introduced.

The results of therapeutic measures in the various stages of syphilis are statistically presented. Recent experiences in the therapeutics of rheumatic fever, rheumatoid arthritis, brucellosis and the menigitides are discussed at length. Results of influenza and BCG vaccinations are presented. The information on hematinics, blood and plasma transfusions, plasma substitutes and blood fractions is inclusive and should prove of help to the clinician. The review on the use and abuse of vitamins and hormones should also prove interesting. A discussion of various insulin mixtures, antithyroid drugs, anesthetic or analgesic substances, cardiac preparations and anticoagulants concludes this volume. The book can profitably be used by the medical practitioner as a good reference guide to accepted and also to some newer therapeutic procedures.

Occupational Medicine and Industrial Hygiene. By Rutherford T Johnstone, A.B. M D, Consultant in Industrial Health, Los Angeles Cloth. Price, $10. Pp. 604 with 117 illustrations. C. V. Mosby Co., 3207 Washington Blvd., St. Louis 3, 1948.

Here is a significant book that is designed, produced and geared to the present day needs of the industrial physician and the general practitioner engaged in industrial medical practice industrial hygienists, industrial health officers, nurses, students and others concerned with the many branches of occupational medicine and industrial hygiene will also be attracted by this most extraordinary source of practical information. The volume, divided into seven parts and forty-one chapters, vividly reflects the unique and extensive experience of the author. Practical data from every important phase of the field are presented in a well written, clear, decisive and conclusive manner.

Of particular interest are the thorough descriptions of the clinical features of industrial diseases, covering signs, symptoms, diagnosis, laboratory procedure and treatment. Case histories illustrate clinical entities. Permanent and temporary disabilities are estimated. In his approach to the industrial solvents Dr. Johnstone has presented a simple review of organic chemistry, thus enabling the reader to grasp the significance of each substance and to classify the various solvents according to their systemic effect. Industrial metals and dusts, including beryllium, are handled with an understanding simplicity that will appeal to the reader. A section devoted to industrial hygiene has been written for the plant physician who has had no training in industrial engineering or hygiene The highly technical aspect of this field has been avoided. The language and descriptions are designed for practical use. In a manner the plant is brought to the physician, thus enabling him to understand health hazards which may exist in connection with such processes as welding, metallizing pickling, heat treating, anodyzing and the manufacture of plastic and synthetic products The preface, written in a typical "Johnstoneian" style, is superb. Definitely, an entirely new contribution to medical literature has been made.

Diabetes Mellitus in General Practice. By Arthur R. Colwell, M.D., Associate Professor of Medicine and Director of Medical Specialty Training, Northwestern University Medical School, Chicago. Cloth. Price, $5.25. Pp. 350, with 24 illustrations The Year Book Publishers, Inc., 304 S. Dearborn St., Chicago 4, 1947.

The practitioner of medicine will be impressed with Colwell's "Diabetes Mellitus in General Practice." It is neat in format and in its content. It is interesting to note that the definition of diabetes, at the beginning of chapter one, reveals the transitory state of knowledge, as far as the underlying cause of the disease is concerned. The old definition with the pentad of symptoms originally described in the Papyrus Ebers, and repeated monotonously up to thirty years ago, is gone; but the definition of tomorrow, the ultimate one, has not yet been written. The background of the diabetic patient is discussed in a satisfactory way. Cases are designated as mild, moderate and severe, depending on the clinical severity of the disease. The time at which diabetes makes its appearance and the severity of the disease receive due consideration. Classification and diagnosis receive adequate consideration, and this gives the author ample opportunity to relate the fruits of his experience. Treatment is divided into treatment in general, treatment by diet and treatment with insulin. Adequate and inadequate modes of therapy are discussed and properly contrasted. This is wholesome in these times when in certain quarters the tendency to liberalism in the control of diabetes is being carried rather far. It is undoubtedly true that some patients seem to have done well for decades without strict control, but no one has yet shown that inadequate control produces as good or better results; and it seems true beyond question that uncontrolled patients show more frequent and more serious complications. Here the author is on solid ground, and his readers will be influenced in the logical direction.

The chapter on insulin and its modifications is thorough and satisfactory. The discussion is at its best, for the author has made valuable contributions to the knowledge of insulin mixtures over the past several years. The distinct value of insulin mixtures, especially the mixing of one part of protamine zinc insulin to two parts crystalline insulin, is emphasized. Complications, acute and chronic, mild and severe, are adequately discussed. This monograph covers the subject in a thoroughly satisfactory way and should be of distinct value to the practitioner of medicine for whom it was intended.

The Practice of Group Therapy. Edited by S. R. Slavson. Foreword by Nolan D. C. Lewis, M.D. Cloth. Price, $5. Pp. 271. International Universities Press, 227 W. 13th St., New York 11, 1947.

In the new field of group therapy nobody can claim rightfully to be an expert yet. Some of the workers have more experience or are more vocal about it—but even the best of them are courageous pioneers, and their work is still in the stage of testing experimentation. Neither methods nor principles are firmly established yet. It is, therefore, highly commendable that S.R. Slavson, as an editor, collected clinical observations and detailed case reports and made them available in his book for the interested newcomer to learn and study the new progress in group psychotherapy. After a short foreword by Nolan D. C. Lewis, the editor, S. R. Slavson, tried briefly to outline the general principles and dynamics. He also wrote a chapter about the "Contra-Indications of Group Therapy for Patients with Psychopathic Personalities."

The best part of the book is the clearcut description of group psychotherapy at work; Nathan W. Ackerman reports it in his chapter about "Interview Group Psychotherapy with Psychoneurotic Adults." Equally informative is the report by James Sonnett Greene, "Interview Group Psychotherapy for Speech Disorders." In a special chapter J. W. Klapman describes "Didactic Group Psychotherapy with Psychotic Patients." Some detailed reports of cases describe adults, children, allergic patients and the treatment of mother-child relations within the group.

The sincere, open-minded and progressive psychiatrist, who at the present time almost desperately attempts to avoid his own breakdown through overwork and who is acutely aware of his responsibility to meet the public demand for adequate psychiatric help, will find in the reports of this book hope and encouragement and guidance to experiment in the practice of group psychotherapy and to experience its potentiality not yet fully recognized and utilized.

Indice bibliografico de lepra 1.500-1.944. Volume II: I-P. Organizado por Luiza Keffer, bibliotecaria do Departamento de profilaxia da lepra de São Paulo, Brasil. Paper. Pp. 675-1434. São Paulo, 1946.

This second volume of the bibliography on leprosy covers the letters I-P and will be welcomed by leprologists and sanitarians. Volume I, covering the letters A-H, was published in 1944. This monumental work compiled by Luiza Keffer, Librarian of the Department for the Prevention of Leprosy of the State of São Paulo, represents one of the largest and most exhaustive bibliographies on any special subject in the field of medicine. Both authors and subjects are included in a single alphabet in dictionary order, an excellent style for quick and easy reference. Since it is a Brazilian publication, each entry is listed in the original language of publication with a Portuguese translation of the title immediately following. A list of the periodicals, with their abbreviations, covered in the bibliography, precedes the index proper.

Diseases of the Nervous System. By W. Russell Brain, D.M., F.R.C.P., Physician to the London Hospital and to the Maida Vale Hospital for Nervous Diseases, London. Oxford Medical Publications. Third Edition. Cloth. Price, $10.75. Pp. 987, with 80 illustrations. Oxford University Press, 114 Fifth Ave., New York 11; Amen House, Warwick Sq., London, E. C. 4, 1947.

Brain's book fills the requirements for a competent textbook on neurology. It has neuroanatomy, neurophysiology and neuropathology, with precise and concise clinical descriptions of all disease entities It is written in the best tradition of English neurology, in which the pervasive influence of Sherrington is felt throughout. Not in vain was the author a "scholar in physiology at the University of Oxford"[1] The book is well balanced; the author is objective, and in no instance does he attempt to impose his own views on the reader, nor does he put forth his pet theories, and he does not display his likes and dislikes. The style is somewhat cold, but the amount of information offered is enormous. It is good for the student, good for the practitioner and good for the diehard neurologist. It is particularly appropriate for the candidates of the American Board of Psychiatry and Neurology as a last minute refresher.

The book is carefully edited, and the number of inaccuracies and misprints is under the physiologic minimum. Here are a few: The cutaneous area of the of the ulnar nerve as shown in figure 4, though taken from an atlas of anatomy, is not correct: this area does not extend proximally above the wrist. Brain states that Erb's syphilitic spinal paralysis is characterized by "absence of sensory loss." Erb himself said in a publication in English of 1902: "Syphilitic spinal paralysis is distinguished from simple spastic spinal paralysis by the presence of disturbances of sensation...." It is regrettable that even such an open-minded man as Russell Brain has succumbed to the prevalent wave of "intervertebral disk hysteria." "Whether true sciatic neuritis occurs is now doubtful: it it certainly very rare...." He speaks of "true" sciatic neuritis. He means, of course, not "true", in contradistinction to "false", but evidently primary neuritis. The existence of such a neuritis has been established beyond any reasonable shadow of a doubt, now and forever—disk or no disk!

The criticism to which this book may be exposed in view of such minor errors in no way detracts from its fundamental value or from its position as the best of its kind. Next to Gordon Holmes's "Introduction to Clinical Neurology," it can be recommended *primo loco* for any student of neurology.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST

INCLUSION BODIES

To the Editor:—Is there any way of distinguishing between Negri bodies and distemper bodies in a section of the brain of a dog? Can both inclusion bodies occur in the same brain? Will anti-rabic treatment cause any congenital defects in a newborn infant if given to the mother in the first trimester of pregnancy? Will anti-rabic treatment produce encephalitis in a child recently recovered from (A) polio, (B) measles or any other virus disease?

M.D., New York.

ANSWER.—Negri bodies and distemper bodies stain differently with methylene blue. The Negri bodies contain characteristic granules. There is of course no reason (so far as we know) why rabies and distemper might not occur in the same dog at the same time when presumably both bodies would be found in the brain.

It is not known whether antirabic treatment early in pregnancy might be followed by defects in the offspring. Neither is it known whether antirabic treatment is liable to cause encepahalitis in a child recently recovered from some other virus disease.

CORNEAL ABRASION

To the Editor:—Please outline the treatment for simple corneal abrasion.

J.E. Walton M.D., Homer, Ill.

ANSWER.—An uncomplicated corneal abrasion, in a healthy person, will heal with amazing rapidity, sometimes within hours, without any treatment. Almost all drugs retard the rate of healing and even ointment bases only tend to soften the epithelium and delay healing.

The first consideration should be removal of the causative agent, whether a misplaced lash, foreign body or conjunctival concretion. An eye patch applied for twenty-four hours will minimize discomfort and this, plus a simple antiseptic, may be all that is required. Severe abrasions may require a cycloplegic as atropine or homatropine to relieve ciliary spasm, and local anesthetics may be required for pain.

TETANY

To the Editor:—I have a patient whose parathyroids were removed incident to a thyroidectomy. As a result she requires frequent injections of calcium gluconate and occasionally parathyroid to control recurrent bouts of tetany. Supplement oral therapy of dihydrotachysterol (A.T. 10) and high doses of calcium lactate by mouth in addition to enteric-coated ammonium chloride are given. The problem at present, however, is a peculiar type of edema to which the patient is subject. She is 22 years old, white, and her thyroid was removed in 1945. The edema is concentrated over the lower part of the abdomen, buttocks and upper part of the thighs. It does not pit. Cardiac and renal function are apparently normal. Profuse diuresis is achieved with injection of meralluride (1 to 2 cc.) daily and every other day. Assuming renal function and serum protein are normal, can any other reason be advanced to explain this type of edema? I would also appreciate any suggestions both as to control of edema and also tetany.

Paul Gerber, M.D., Philadelphia.

ANSWER.—The type of solid edema is seen in some persons who have toxic diffuse goiter (Graves' disease) which is much like that described in the patient. It is almost always symmetric, usually involves the shins, does not pit and appears much like pigskin. A small biopsy specimen taken from an involved area should show the characteristic myxomatous changes and edema in the cutis, as well as homogenized collagenous tissue. Although this process is called localized myxedema, it does not respond to dessicated thyroid as does generalized myxedema. It may be present with an associated elevated basal metabolic rate or it may appear when the basal metabolic rate is normal or low. Its etiology is probably related to the thyroid-stimulating hormone of the pituitary gland.

Dihydrotachysterol plus calcium lactate by mouth is good treatment for hypoparathyroidism. The dose of the former should be adjusted so that enough is taken each day to maintain a blood calcium level near the normal range of 9 to 11 mg. per hundred cubic centimeters. The tolerance of the individual patient of this drug is variable, and its action is slower than parathyroid, but more rapid than vitamin D2. A starting dose of 1.25 mg. daily can be given and then the amount increased or decreased, based on the behavior of the serum calcium and the patient's symptoms.

PROLAPSE OF RECTUM

To the Editor:— Is the injection treatment, as recommended in Medical Record 149:273 (April 19) 1939, for large complete rectal prolapse a recognized procedure? The patient is a woman aged 73 with first-sized prolapse of the rectum. She had recurrences after colopexy and circular scar-formation operation.

M.D., Kansas

ANSWER. Perhaps the only instances in which injections of a sclerosing solution are useful in prolapse of the rectum are in children. There the procedure outlined by Harvey Stone of Baltimore with the injection of alcohol will sometimes effect a cure. In complete rectal prolapses in adults quinine and urea hydrochloride would be contraindicated because of its well known tendency to cause sloughs and because fundamentally it is not the mucosa alone which is prolapsed but all layers of the bowel.

MENINGITIS

To the Editor:—In the recent Volume II of the "Cornell Conferences on Therapy" (New York, the Macmillan Company, 1947) on the subject of meningitis, it is emphasized that after a spinal puncture more spinal fluid should always be withdrawn than the amount of therapeutic material injected (penicillin, for instance). Other textbooks on the technic of lumbar puncture emphasize this. Best, in the "Physiological Basis of Medical Practice," states that the spinal cord membrane and brain coverings and channels are capable of considerable expansion. Having personally treated several infants with meningitis and at times being unable to withdraw as much spinal fluid as I would like, I have proceeded to inject more penicillin solution than the amount of spinal fluid withdrawn. I have seen no bad effects on any of the children. It is my opinion that this caution in regard to withdrawing more spinal fluid than the amount to be injected is more theoretic than real. Kindly give me an opinion.

M.D., Ohio.

ANSWER.—The question of whether to withdraw more spinal fluid than the amount of substance to be injected is of secondary importance to the question of whether any should be injected at all. It is reasonable and theoretic, of course, to assume that if the pressure of the spinal fluid is already increased, as it often is in meningitis, any greater increase in pressure from even more fluid may be harmful despite the ability of the membrane to expand. Although many authorities still favor the use of spinal drainage and intrathecal therapy for meningitis, A. L. Hoyne and others for years have shown that the less the theca vertebralis is tampered with, the better the mortality rate. In a recent series of cases (*Ann. Int. Med.* 28:248, 1948) the mortality rate among 660 patients with meningococcic meningitis was 6 per cent, and only 2 of 28 patients with meningitis due to Haemophilis influenzae died (THE JOURNAL, February 28, p.597). The great majority of those who recovered did not receive intrathecal therapy, and in the meningococcic cases spinal tap was never done if the diagnosis could be established by blood culture or culture from the dermal lesions. According to A. H. Price and J. H. Hodges (*New York State J. Med.* 44:2012, 1944), it seems to be more important to direct penicillin into the tissues of the meninges, where the infection is, than to attack the bacteria which float in the spinal fluid; and to do this parenteral therapy is preferred.

INTERVERTEBRAL DISK

To the Editor:—A brief history of a patient is as follows: Onset occurred with acute pain low in the back and sciatica six to seven years ago. At that time an orthopedist attributed the condition to a sacroiliac strain. The acute symptoms subsided, leaving a chronic sciatica which was aggravated and accompanied by "lumbago" (left lumbar) on exertion, such as lifting. A second orthopedist two years later concluded that the original lesion had been injury to a disk. Last summer a severe attack of lumbago caused the patient to consult another orthopedist, who agreed that the basis of the trouble was a lesion in a disk and suggested that removal plus fusion would be necessary if the patient wanted to be active and comfortable. Since the last consultation, the patient has complained of his buttocks' and legs' "going to sleep" after sitting for ten minutes or more. There is more or less constant paresthesia of the right leg and particularly the outer side of the foot. Why should this get worse and appear in the opposite leg (not as marked) when sitting? Is there a correlation with the injured disk? Crossing the legs tends to aggravate the condition, but it is not prevented by not crossing them. The patient is a white man aged 35 years who is rather thin (6 feet 1 inch [185.4 cm.] and 150 pounds [68 Kg.]). He does office work requiring intermittent sitting of one half to one hour or longer. Information on literature, diagnosis and treatment is requested.

M. D., Virginia.

ANSWER.—The data supplied indicates an involvement of the lumbosacral roots. The history indicates a rather long duration of symptoms referable to the roots on the right, and more recently an extension to those on the left. The presumption would be that the basis for the symptoms is a disturbance of the intervertebral disks. This is predicated on the distribution of the signs and and symptoms, the absence of sphincter disturbance and the clinical course. This may be either a ruptured nucleus pulposus or a partial extrusion of the entire disk.

The paresthesia that develops in the buttocks and legs after sitting is probably the result of increased pressure against the lumbosacral roots as a result of posture. The distribution of the paresthesia is important, because if it is referable to pressure on the lumbosacral roots then it should be present over the buttocks, down the backs of the legs and over the lateral aspect of the feet. The increase of symptoms in the syndrome of irritation of the lumbosacral roots by the sitting position is not uncommon, as witnessed by the discomfort that these patients have in driving a car and the not unusual relief of symptoms when they stand.

Taken as a whole, in a sciatic syndrome, the appearance of signs and symptoms indicating bilateral involvement of the lumbosacral roots is an indication for surgical intervention. A sudden twist or strain may at any time so greatly increase the pressure against the roots as to produce serious changes which will greatly interfere with recovery. While conservative treatment is possible and frequently sufficient in unilateral syndromes, surgical treatment is recommended when the signs and symptoms are bilateral.

The book on intravertebral disk by Spurling (Bedford, F. K. and Spurling, R. T.: Intervertebral Disc, ed. 2, Springfield, Ill., Charles C. Thomas, Publisher, 1945)

CALCIUM AND OXALIC ACID IN ARTHRITIS

To the Editor:—Arthritis has such a large scope, I would like to know what role calcium or its salts have in its development. Is oxalic acid or any of its salts ever used in the treatment of arthritis?

C.C. Lull, M.D., Beaver City, Neb.

ANSWER.—Because atrophy of epiphysial bone occurs often in rheumatoid arthritis and osteophytes (bony spurs) develop in osteoarthritis, physicians through the years have entertained the idea that some disturbance of calcium metabolism may be related to chronic arthritis. But no definite evidence of any such disturbance has ever been produced, and the concentrations of calcium in blood and urine of arthritic patients are generally normal. The bony spurs of osteoarthritis and the epiphysial atrophy of rheumatoid arthritis are believed to result from local, not general, abnormalities.

The level of oxalic acid in the blood of patients with various rheumatic and arthritic complaints has apparently interested a few foreign physicians for many years. The literature on this subject has been summarized recently by Jozef Grott, F. Kowalski and S. Windyga (*Acta med. Scandinav.* 125:576-587, 1946). These workers also reported their observations on the oxalemia of 402 patients. Included were 7 patients with "polyarthritis deformans," but the oxalic acid level is stated specifically in only "3 cases of severe polyarthritis deformans and 1 case of spondylarthritis deformans"; in all of these a normal level of oxalic acid was found In 4 of 9 patients who had Heberden's nodes the level of oxalic acid in the blood was increased.

From the evidence at hand there appears to be no rationale for the use of preparations of either calcium or oxalic acid in the treatment of any type of arthritis. There is no satisfactory evidence that the empiric use of any calcium preparation has been of value. No report on the use of oxalic acid in treatment of chronic arthritis has been noted. An account of the current conflicting views with regard to oxalic acid is contained in an editorial in THE JOURNAL (133:1010-1011 [April 5] 1947). In general "the biologic significance of oxalic acid requires more clearcut definition," but it may be pertinent to point out that the formation by oxalic acid of a highly insoluble precipitate with calcium (calcium oxalate) "is said to account for some 40 per cent of the cases of urolithiasis."

SAFE DRIVING

To the Editor:—1. What is safe vision to qualify one to drive a car? 2. Are vision tests as carried out by the motor vehicle bureaus satisfactory even though vision may be excellent on the test chart? 3. What is adequate road lighting for night driving on an express highway within city limits? 4. For an express highway within city limits demanding more speed than on ordinary streets should illumination be proportionately increased and evenly distributed to reduce the danger of accidents, especially when road illumination is poor and dimming of auto lights is compulsory? 5. What candlepower as measured on the roadway is safe and adequate in relation to allowable speeds? There is at present a campaign in New York to serve summonses on many drivers for "improper driving lighting." I believe that such a campaign is fraught with danger.

Emanuel Krimsky, M.D., Brooklyn.

ANSWER:—The visual requirements demanded of automobile drivers vary considerably in the several states that have regulations—from a minimum of 20/30 vision in both eyes without glasses to 20/70 vision in one eye with glasses. A committee of the American Medical Association suggested as minimal standards: visual acuity correctable to 20/40 in one eye and 20/100 in the other; form field of not less than 45 degrees to both sides laterally from dead center ahead; binocular single vision; ability to distinguish red, green and yellow, and glasses if required to be worn while driving. The Minimum Driver License Examination Standards recommended by the American Association of Motor Vehicle Administration in 1939 are: minimum vision of 20/60 in one eye or both eyes, glasses to be worn if necessary to attain this vision; ability to read and understand highway signs regulating traffic. The Interstate Commerce Commission demands that drivers in interstate commerce have a corrected vision of at least 20/40 in one eye and 20/100 in the other, a form field of at least 45 degrees in all directions and the ability to recognize red, green and yellow.

The Illuminating Engineering Society, 51 Madison Avenue, New York, recently published a booklet on "Recommended Practice of Street and Highway Lighting" which is available for 50 cents. The lighting recommendations depend on the width of the roadway, the density of traffic and the traffic hazards present. About 1 foot-candle measured on the roadway is generally considered safe and adequate. Improved road lighting always gives a reduction in accidents. In 1938 New Jersey checked and revised the road lighting in the state, with the results that there were 37 per cent fewer night accidents than in the previous year.

ADRENAL CORTEX EXTRACTS

To the Editor:—I should like information on the value of adrenal cortex extracts in peripheral circulatory failure in acute infections, uremia and pneumonia.

Georges-Henri Jurcot, M.D., Montreal, Canada.

ANSWER.—Although animal experimentation suggests that adrenal cortical extracts, as well as synthetic corticoids, play an important role in the defense against various types of nonspecific stress, the results obtained in patients with peripheral circulatory failure, acute infections, uremia and pneumonia are not encouraging. This may be due to the fact that the adrenal cortex normally produces adequate amounts of corticoids so that exogenous hormone administration cannot improve the situation significantly because corticoid deficiency is not the "bottleneck" in such cases. At present the administration of adequate quantities of the so-called glucocorticoid compounds (those especially involved in the mechanism of gluconeogenesis from protein) is not yet possible because of their restricted availability. Somewhat more encouraging results have been obtained in severe burns and traumatic shock when large doses of cortical extract were given (Selye, H.: *J. Clin. Endocrinol.* 6:117, 1946). It is suggested that, except for experimental purposes, the use of corticoids for the treatment of the forementioned conditions be postponed until adequate amounts of the pure crystalline compounds become commercially available.

CLICKING OF HEART

To the Editor:—A woman, aged 29, has complained of a "throbbing of her heart" at which time a "clicking" noise is heard with approximately each heart beat. This is produced only when she lies on her left side, usually when she is lying on a sofa with the head on the arm of the sofa. This noise can be heard without a stethescope at a distance of about 3 feet (91 cm.) and sounds as if a piece of stiff "celluloid" is being popped or bent. Pressure on the precordial area causes the noise to disappear. There is no pain associated with it. The clicking is heard at the same rate as the heart beat but does vary as to whether it appears at systole or disastole; i.e., it is not rhythmical with the heart beat. This clicking may be heard in groups of three, then pause, or miss, then another run of six to eight, then pause; i.e., it is not constant, but when it does appear it is consistent with the heart beat. Auscultation of the heart is normal except when the "clicking" appears, at which time the heart beat sounds booming and loud. One examiner suggested that it was gas and possibly a diaphragmatic hernia. Another said that it possibly is the so-called "xiphomanubrial noise," to which I cannot find any reference. Roentgen examination of the chest and partial gastrointestinal series were negative. Please mention the possibilities and where I might find reference to "xiphomanubrial noise." The past history of the patient is entirely negative.

E. R. BARBER, M.D., Lancaster, S.C.

ANSWER.—The auscultatory phenomenon described is unusual but is undoubtedly of extracardiac origin. Its character and variability with position and respiration suggest the movement of air in adjacent lung tissue synchronous with the heart beat. Hammond has described a somewhat similar sound disappearing in a few days following acute mediastinal emphysema. However, the described situation does not resemble that clinical syndrome. It is possible, but most unlikely, that the movement of fluid and air in the stomach might be responsible. In any event, the absence of demonstrable disease in the heart, lungs and upper part of the gastrointestinal tract indicates that this sound is probably unimportant as far as organic disease is concerned. The "Xiphomanubrial noise" mentioned in this query has been described and the literature reviewed by M. Solis-Cohen, in an article entitled "Xiphosternal Crunch and Its Incidence in Healthy Inductee," *Am. J. M. Sc.* 210:333-342 Sept 1945.

DEMENTIA PARALYTICA

To the Editor:—A physician patient, aged 48, has been under treatment since December 1941 for dementia paralytica. Symptoms appeared with persistent headache followed during 1942 to October 1943 with hallucinations, amnesia and agraphia. He became untidy and dull, wandered the streets and, half dressed, entered the homes of neighbors. In November 1943 he started malaria therapy. From March 1944 to July 1946 he took a course of tryparsamide, total 125 Gm. and bismuth subsalicylate, 50 cc. In March 1945 epileptic fits began. In October 1946 he began a course of penicillin therapy, 2,400,000 Oxford units. In January 1947 he started fever therapy with typhoid vaccine in combination with calcium penicillin in oil and wax ("delacillin," Squibb), 5,000,000 Oxford units. The epileptic fits continued on and off. I have prescribed diphenylhydantoin sodium. Now my patient has improved considerably, but I feel that I should completely rid him of his attacks so that he may resume work. Is there a later more effective remedy for his condition?

C.Y. Wu, M.D., Shanghai, China.

ANSWER.—The first requirement is complete control of the neurosyphilis. From the recorded data, it is presumed that the patient has had sufficient treatment to arrest the syphilitic process. A more recent examination of the spinal fluid than that recorded as of December 1946 would be useful in establishing this fact. A normal cell count and total protein should be obtained within six to twelve months after fever therapy and penicillin therapy. The epileptic seizures are probably residual symptoms of cerebral scarring. If reexamination of the spinal fluid shows abnormality in cell count and total protein, another course of penicillin to the amount of 6,000,000 units, given intramuscularly over a period of no less than fifteen days, might be advisable.

For direct control of seizures, anticonvulsant drugs may need to be used to the point of toxicity: diphenylhydantoin sodium ("dilantin") 0.4 or 0.5 Gm. daily, combined, if need be, with phenobarbital, 0.1 to 0.2 Gm. or else methylphenylethyl hydantoin ("mesantoin") 0.3 to 0.6 Gm., alone or combined with "dilantin."

ORTHOSTATIC ALBUMINURIA

To the Editor:—The question concerns (1) orthostatic albuminuria, (2) adolescent menorrhagia and metrorrhagia and (3) the possibility of etiologic connection between these two conditions. A white girl aged 16, of tall and slender build, consulted me several months ago because of continuous vaginal bleeding for the past four months. General physical examination revealed essentially normal conditions except for pallor and small size of the uterus, as determined by rectal examination. The patient is a virgin. Laboratory studies disclosed a secondary anemia; the urine contained plenty of albumin but no casts. Blood urea nitrogen and creatinine determinations were within normal limits, as was the blood pressure. The albuminuria was of the orthostatic type, and urine secreted by the kidneys while the patient was in the recumbent position did not contain a trace of albumin. The tuberculin patch test was negative. Roentgen examination of the chest revealed normal conditions. The plasma proteins were 7 per cent with a normal albumin-globulin ratio. A diagnostic and therapeutic curettement of the uterus was performed. The pathologic report stated that the endometrium resembled that seen about the tenth day of a normal menstrual cycle, there was cystic dilatation of endometrial glands, possibly hyperestrogenemia. The girl received two Rh-compatible blood transfusions and was discharged. A high protein diet, iron and vitamins by mouth, plenty of rest, 1 Gm. thyroid daily, (the best metabolic rate was normal), and injections of the progesterone, 10 mg. twice a week, were recommended. During the past four months she has gained 10 pounds (4.5 Kg.). Her blood count has remained normal and she feels well, but she still has frequent, fairly profuse and irregular uterine bleeding. Bleeding time, coagulation time, prothrombin time and platelet counts were normal. Because of my suspicion of a tuberculous renal and genital infection a retrograde pyelogram was done, which showed good function of both kidneys and evidence of a minimal, healed pyelonephritis on the right side. " Tween 80" culture of the catheter urine was negative. My questions are these; 1. Is the continuous loss of rather large amounts of albumin in the urine harmful to the patient's general health? 2. Is there any additional safe treatment for this girl's metrorrhagia, which will not deprive her of the ability to become pregnant? 3. Is there any possible etiologic connection between the orthostatic albuminuria and the metrorrhagia?

M.D., Washington.

ANSWER.—Orthostatic albuminuria usually occurs in young persons who have poor muscular tone and pronounced evidence of vasomotor instability. The prognosis is good, because in many cases the condition disappears as the general health improves. 1. The replacement of the albumin lost in the urine by proper diet generally prevents harm. 2. There need be no fear that the patient's abnormal bleeding or the endocrine treatment used to try to over come it will prevent subsequent pregnancy. Endocrine therapy, unfortunately, is generally not successful. It does little harm and this is nearly always temporary. Roentgen or radium therapy, which is occasionally used, can do irreparable harm if the dosage is too great. In nearly all cases the use of proper diet, iron, vitamins and blood transfusions aided by either anterior pituitary-like hormone, progesterone, estrogens or testosterone propionate suffice to tide the patient over until the condition is rectified. 3. As far as is known, there is no connection between orthostatic albuminuria and menorrhagia

MERCURY AND SULFUR PRESCRIPTIONS

To the Editor:—Books on dermatology are loud in their warnings with regard to the incompatibility of prescriptions that contain compounds of mercury and sulfur. In what way are preparations containing these two elements incompatible, chemically or clinically? What bad results may be caused by the simultaneous use of prescriptions containing them?

M.D., Missouri.

ANSWER.—The principal incompatibility between compounds containing mercury and compounds containing sulfur is chemical in nature. Prescriptions containing mixtures of such compounds may tend to become pharmaceutically inelegant and lose therapeutic potency through the formation of black insoluble mercuric sulfide or free mercury. This is especially true of compounds in which the mercury is loosely bound and in which sulfur is present in low stages of oxidation. No harmful effects may be ascribed to the concurrent use of separate prescriptions containing mercury and sulfur compounds, respectively, but it is possible that the therapeutic efficiency of either prescription might be reduced.

TUBERCULOSIS

To the Editor:—A few additions might be appended to the section labeled " Tuberculosis" in Queries and Minor Notes, THE JOURNAL, January 3, page 70. The questions were by a Portsmouth, Virginia, physician. 1. It was wise to stress that minimal pulmonary tuberculosis is often infectious, even though to a minor degree. Stiehm's careful work showed that bacilli could be found if they were searched for in the gastric washings (70 per cent), but Sanford found them in 86 per cent of 105 active minimal cases; laboratories are now obtaining even higher figures where a routine intensive search can be made by several methods over a period of months. 2. Alcohol has recently been found to be much more valuable against the tubercle bacillus than was formerly thought (C.R. Smith, *Pub. Health Rep.* 52:1295 [Sept. 5.] 1947). The information is not yet generally known. Various strengths of ethyl and isopropyl alcohol were tested on tubercle bacilli in wet and dry mediums. The mediums included sputum, and the conditions were probably more stringent than would be encountered in a heavy droplet or dust contamination. The results revealed that tubercle bacilli are quite sensitive to alcohol, and that it is a good antiseptic. Some strengths are more effective than others in certain circumstances. Ethyl alcohol, 95 per cent, is bactericidal in fifteen to thirty seconds against wet bacilli; 50 per cent is the more effective strength against dry smears, 70 per cent is probably the best all purpose dilution. Isopropyl alcohol is at least as effective as ethyl, and even more so in 50 to 70 per cent dilutions. The amount of the sputum substrate did not appreciably delay the effects. Most of the bacteria were killed in the first few seconds. Practically, 70 per cent ethyl alcohol may be used with confidence on dry hands, or after washing; the alcohol should be allowed to dry on the hands in the ensuing thirty to sixty seconds. Plain inexpensive "rubbing alcohol" (50 to 70 per cent isopropyl) is as good or better. They may both be used to sterilize small objects or surfaces (provided that the material will not be injured), to rinse rubber gloves while in use, and in thermometer containers. The odor is not bad or lingering, and there is no residue. 3. Information on the effect of cresols is archaic and unsatisfactory. Apparently, nothing has been done for years to determine the effects of solutions of less than five per cent, or for times of less than five minutes either by private or by commercial investigators. The available experiments (mostly in Germany) used heavy masses of sputum, a situation which is not applicable to current needs. References to cresol as the antiseptic of choice against the tubercle bacillus must be modified by the data on alcohol, and proved by new tests in which high dilutions and "dust and droplet" conditions are simulated. The low cost and the cleansing action of the cresols make them potentially important. Incidentally, more work could be done on the relative efficiency of masks, on the use of oil on floors and on the development of an odorless cresol. A manual of the American Hospital Association (*Oatway, W. H., Jr.*: " The Management of Tuberculosis in General Hospitals," Chicago, 1939) contains a complete isolation technic, but certain procedures had to be included which were derived from contagious disease technic and are not completely proved for tuberculosis work. 4. I do not believe that there is any report extensive enough to truly show the percentage of physicians who contract tuberculosis while working in sanatoriums. Most data on professional contact infection and disease have been obtained by examination of physicians and medical students in general hospitals or sanatoriums. The data show that continued contact with patients, or tuberculous patients, will produce increasing amounts of infection and disease but that it is possible to minimize these factors by a strict isolation technic. The answer to the remainder of the problem is to employ only persons with positive reactions to the tuberculin test or to use BCG vaccine, an efficient and more feasible method.

W.H. Oatway Jr., M.D., Los Angeles.

NECK SURGERY AS RELATED TO OTOLARYNGOLOGY

C. H. McCASKEY, M.D.
Indianapolis

Neck surgery in otolaryngology has not been developed to any great degree. It is open to development at present, and it is my hope that in the future increasing numbers of otolaryngologists will adopt this field of surgery as their responsibility. Some instructors not only teach neck surgery along with otolaryngology, but they also advocate that the otolaryngologist should follow a definite program of training in this field. A year in general surgery should be added to his training; in his basic subjects he should be taught gross and surgical anatomy, as well as the surgical pathology and histopathology of the neck; and, under the direction of a good teacher, he should be guided in the practical application of this knowledge.

In particular, certain features of the anatomy of the neck should be stressed, among the most important of which are the cervical fasciae. Because of their great clinical importance, the study of these fasciae in the cadaver is insufficient. The otolaryngologist should be impressed with the difference between the fasciae he sees in the cadaver and those which exist in the living body. Histogenetically, the fasciae are composed of the same type of connective tissue cells that enter into the formation of the supportive framework and the covering of the muscles, blood vessels, nerves and viscera. They are morphologically identical with the periosteum and muscle tendons and with the supportive framework of serous membranes. As a matter of fact, the fasciae cover and blend with the external coat of all the important organs of the body, i. e., blood vessels, nerves, bones, muscles and most of the viscera. The fascial interspaces serve as paths of least resistance for the spread of infection, neoplasms and foreign bodies. Only with a comprehensive knowledge of these fasciae is the otolaryngologist well fitted to perform operations on the neck.

Before proceeding, perhaps it would be well to define what is meant by the neck. It may be said, with a certain degree of safety, that the neck is the isthmus which connects the head with the body; therefore, it must be of great importance, as not only does it carry the cervical vertebrae, which support the head, but also through it pass the airway, the food passages, the great blood vessels, the lymph nodes and salivary glands and many of the cranial nerves. Even the upper end of the esophagus must be considered part of the neck. Each of these structures is subject to certain infections and pathologic changes. It is apparent, then, that the otolaryngologist's knowledge of the disorders which occur in the neck should be definite and broad in its scope. Actually, the neck may be, and often is, the seat of pathologic changes, which may produce as many surgical problems as, if not more than, any other portion of the body. Certain of these problems, which in the past have been left to the general surgeon, are now thought by many physicians to belong in the field of otolaryngology. It is increasingly important, therefore, that the otolaryngologist have adequate training in the management of these problems of neck surgery.

All too often neck surgery is thought of as applying only to those diseases which are approached by opening the neck externally, but in the true sense this is not so. For instance, a tonsillectomy is considered a surgical procedure on the pharynx; but, inasmuch as the pharynx is included with the neck, a tonsillectomy may be classified as an operation on the neck. (This example is used only for the purpose of illustrating that any discussion of neck surgery in otolaryngology should include all those structures which are part of the neck.) Stated in another way, the otolaryngologist who does not recognize the surgical procedures for tumors of the neck as just as much a part of his field of work as a tonsillectomy should at least consider this larger view of neck surgery.

It has been said that what a disease is, what it is thought to be and what it ultimately proves to be are nowhere in all pathology so well illustrated as in this part of the body. The early recognition and the proper management of the many disorders in the neck with which the otolaryngologist is frequently confronted call for a thorough knowledge of the anatomy of the regions concerned and of the diseases and injuries which may occur in them. The greatest difficulty one meets in making conclusive diagnosis is in the preoperative differential diagnosis of the lesions. In general, the most commonly encountered conditions necessitating operations on the neck fall into the following classification: primary tumors, secondary tumors, congenital diseases of the neck, infection of the salivary glands and inflammatory infections of, and traumatic injuries to, the neck.

Primary tumors of the lymph nodes are seen in cases of Hodgkin's disease, lymphosarcoma and lymphoepithelioma. In Hodgkin's disease, or Hodgkin's granuloma, there is an involvement of the lymph nodes in which one or more of them are enlarged; in the majority of cases a single node is affected, usually one

Read before the Section on Laryngology, Otology and Rhinology at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N.J., June 12, 1947.

in the posterior triangle of the neck. Many times a patient with such a condition presents himself to the otolaryngologist, with a history of acute tonsillitis or infection of the upper respiratory tract, causing the patient to think that the enlargement of the lymph node was secondary to the infection. Definite diagnosis must be made by biopsy, but surgery offers the patient little hope of a cure. In cases of lymphosarcoma, surgical intervention may be of value if the tumor is removed while it is small. Lymphosarcoma of the nodes of the neck usually appears in the posterior triangle or under the upper third of the sternocleidomastoid muscle, although later it may invade such structures as the esophagus or the larynx. Lymphoepithelioma occurs typically in the anterior triangle under the angle of the jaw, protruding under or anterior to the sternocleidomastoid muscle. In some cases, the lymphoepithelioma is preceded by a tumor of the pharynx. The termination of this tumor, if it is not removed by early operation, is a functional disturbance or destruction of the organs of the neck by direct invasion.

Secondary tumors of the neck that may be encountered include metastases from malignant growths in the buccal cavity, direct extension from the buccal cavity and metastases from lesions below the clavicle. These secondary tumors may be defined as deposits of malignant tissue lodged in lymph nodes of this region, and coming from primary tumors situated somewhere in the area of drainage. Surgical treatment of these tumors, if carried out, must be radical and extensive.

Congenital diseases of the neck occasionally produce cysts in vestigial structures, aberrant tumors (notably of the thyroid gland) and tumors of the carotid sinus. Cysts of the thyroglossal duct may extend as low as the sternal notch, and they usually end in the base of the tongue. The treatment of these growths is surgical. Branchiogenic cysts also occur. These lesions develop gradually without disturbance and may furnish the basis for malignant epithelial growths. Again the treatment is surgical; irradiation has been unsatisfactory. Branchiogenic fistulas may extend from the lateral wall of the pharynx to the skin in the region of the sternal notch. Any portion of these fistulas may exist; the opening may be near the sternum, in the middle of the area, or in the pharynx. Surgical treatment is necessary, and this must be complete. Tumors of the carotid sinus are rare and not well understood. It is important to remember in connection with these tumors that when operated on early they are easily removed, but if operation is delayed they are disposed to involve the carotid vessels and often become inoperable.

Disorders of the salivary glands also may be brought to the attention of the otolaryngologist. The physiologist would classify these glands as part of the digestive system, but the pathologist would classify them as [illegible] of the neck. Various tumors, [illegible] growths and inflammatory processes may affect the salivary glands. The submaxillary and parotid glands are the ones with which the otolaryngologist has oftenest to deal because of infection and the blocking of drainage with stones; also, the tip of the parotid gland may become involved when the hair follicles or the ceruminous glands of the external auditory canal are infected.

Inflammatory infections of the neck are common. The tonsils, the cervical vertebrae, the nasal sinuses, the temporal bone and the mastoid cavity, the teeth and the esophagus and respiratory tract are often the sources of infection of the neck. Acute lymphadenitis follows an infection, usually one of the upper respiratory tract. Ordinarily, a single lymph node is involved to the extent that drainage has been blocked. Surgical treatment with incision of the skin and blunt dissection to obtain drainage is necessary. Cellulitis of the floor of the mouth (Ludwig's angina) is another infection of the neck. It may be regarded as an intensely infectious phlegmon occurring under peculiar anatomic conditions. Dental infection is the commonest cause. The surgical treatment of this condition is radical and should be undertaken early. Abscesses of the pharyngomaxillary fossa are common and usually originate from infection in the tonsil, parotid gland or tip of the mastoid process, from a retropharyngeal abscess or from vertebral caries. Dr. Harris P. Mosher described the approach to this fossa when it is infected; his is still the classic method of approach for its drainage.

Trauma of the neck includes injuries to the muscles, blood vessels, larynx and esophagus. These injuries may be slight, or they may be serious in their nature. Many times the surgeon is called on to carry out rapid surgical procedures in repairing these injuries, and he must make quick decisions in order to save a life.

It may be noted that the problems of neck surgery arising in most of the conditions just enumerated may be encountered frequently in the practice of otolaryngology, and, in many instances, they are closely related to other problems in this field. The surgical procedures on the neck associated with otolaryngology will be familiar to most practitioners, although a few deserve brief mention at this time.

In surgery of the blood vessels, the procedure with which the otolaryngologist is most concerned is ligation of the blood vessels in the neck to control hemorrhages. The vessels most commonly ligated are the common carotid artery, the external and internal carotid arteries and, at times, the lingual artery.

The King operation for the relief of abductor paralysis of the vocal cords is an important surgical procedure. This operation was created and described by Dr. B. T. King; later, it was modified by him, as well as by other surgeons, namely, Kelly, McCall, Furstenberg and Woodward, each adding something to improve the technic.

One of the most important surgical procedures on the neck is the subtotal laryngectomy for cancer of the larynx. This operation is probably the most formidable one the otolaryngologist is called on to perform, and it requires the highest degree of skill at his command. One should not undertake this procedure without thorough training in the technic.

Laryngofissure is a second surgical procedure for cancer of the larynx. It is not so formidable as a laryngectomy; nevertheless, it requires great knowledge of surgical technic.

Repair of the hypopharyngeal diverticulum is a surgical procedure which should be undertaken by the otolaryngologist. It is not too difficult a technic, but it requires the teamwork of the surgeon and an endoscopist to carry out the procedure successfully. It should be a one stage operation.

I am purposely omitting surgery of the thyroid gland from this discussion because the gland is so closely related to internal medicine that I feel its surgical treatment should be left to one who is intimately acquainted with this field of practice and its associated problems.

Lesser types of surgery of the neck could be mentioned, but time will not permit.

CONCLUSION

The otolaryngologist should be prepared to perform more surgical procedures on the neck.

His preparation should include a comprehensive knowledge of the histopathology and surgical anatomy of the neck, with special stress on the cervical fasciae. This area may present more surgical problems than any other area in the body.

A keen knowledge of surgical technic is extremely important.

20 North Meridian Street (4).

ABSTRACT OF DISCUSSION

Dr. August L. Beck, New Rochelle, N. Y.: Dr. McCaskey has called attention to the gap between the field of otolaryngology and that of general surgery. As knowledge of disease affecting the viscera of the neck has advanced, it has become increasingly evident that many abnormalities of these organs can be dealt with only through an external approach. One of the best examples is a pharyngomaxillary abscess which has eroded an artery. With such a condition, incision of the lateral pharyngeal wall through the mouth probably would promptly be fatal. The otolaryngologist should possess a thorough knowledge of the functions and diseases of the viscera in his field as well as of the anatomy of the head and neck. Thorough familiarity with the following topics as they pertain to the neck is necessary for intelligent treatment of disturbances in this region: portals of entrance of infections, descriptive and applied anatomy, symptomatology, functions of all structures in the head and neck and complications and related systemic manifestations. Basic training in general surgery is imperative, but training in general surgery without training in otolaryngology is not enough to enable the surgeon to deal intelligently and accurately with all the problems of neck surgery. I agree with Dr. McCaskey that surgery of the thyroid gland is best left in the hands of the general surgeon because of the systemic disturbances which result from its derangement. On the other hand, if the qualified otolaryngologist is familiar with the entire subject of diseases of the thyroid gland there is no reason for his not performing surgical procedures involving it. Likewise, treatment of diseases of the cervical portion of the spine is best left in the hands of the orthopedist. If infections and abscesses of the fascial plane involve the surrounding soft parts, the problem becomes one which the otolaryngologist should be best qualified to manage. Pharyngomaxillary, or parapharyngeal, infections, as well as cellulitis of the floor of the mouth, which is somewhat severer on one side, may always be reached by Mosher's approach to the submaxillary fossa. Sublingual and submental cellulitis is most easily and directly reached through the suprahyoid midline approach, and no important structures are encountered in the procedure. Infections predominant in the posterior triangle are reached through an approach in that area, behind the sternocleidomastoid muscle. In cases in which preliminary tracheotomy is necessary, the otolaryngologist is best qualified to make the decision and to perform the operation. Dr. McCaskey has pointed out that recognition of structures in the neck in the presence of disease is sometimes more difficult than recognition in a cadaver. This statement is true. One must acquire the ability to recognize swollen, inflamed, distorted and displaced structures in making surgical approaches in the living patient. The otolaryngologist with good surgical skill can equip himself to work intelligently and successfully in this field.

Dr. Joseph W. Kelly, New York: Dr. McCaskey's paper is an excellent plea to the young otolaryngologist to qualify himself in this branch of surgery. I cannot understand why neck surgery is more open to development now than it has been at any time in the past. With the advent of the antibiotic drugs, the necessity for use of the radical procedures in treatment of infections of the neck has practically fallen into the category of the radical mastoidectomy. Ligations of the jugular veins and the procedures on the carotid sinus and on jugular vessels used in treatment of the old acute mastoiditis are gone. The cases of free and open damage to the neck accompanying infections of the floor of the mouth, with edema of the larynx and the necessity of tracheotomy, resulting in secondary pneumonia and death, have been few in the last ten years. When I remember that the last 6 patients with meningitis under my care at Bellevue Hospital recovered, I realize what a far cry the situation of today is from that of the twenties and thirties. When I read papers written by men of this society advocating the closed treatment of the periesophageal abscess, or inflammation, with penicillin and sulfonamide compounds, I wonder that it is necessary to make a special study of the fasciae of the neck. Occasionally I now have to drain a localized abscess, but the sleepless nights of terror spent in treating infections of the neck are, in my opinon, a thing of the past. I cannot agree with Dr. McCaskey that tonsillectomy should be included with surgical procedures on the neck, nor should I consider the closing of a cleft palate in this category. Operations for extensive deep malignant neoplasms of the neck are the most discouraging in neck surgery. The surgeon suffers, and the patient suffers excruciating pain if the branchial plexus is involved. I strongly advocate dissecting a gland to make a diagnosis in cases of neoplasms of the neck. Branchial and thyroglossal fistulas and cysts, in my opinion, are well within the field. I do not know of more satisfying and satisfactory surgical results than those obtained with the proper performance of these procedures. It is almost as satisfying as removing a trachectomy tube after an arytenoidectomy. In the surgical treatment of cancer of the larynx, less work, but more judgment, is required to perform a laryngofissure than a laryngectomy. The receptive student can be taught the technic of laryngeal surgery, but it is difficult at times for the teacher not to err on the side of conservatism. Dr. McCaskey feels that the hypopharyngeal diverticulum should be repaired in a one stage operation. I must plead guilty of doing it in one stage for convenience, but I believe that the two stage Leahy procedure is the better surgical technic. I, too, strongly urge more training in neck surgery for otolaryngologists. We at the Manhattan Eye, Ear and Throat Hospital have been trying to accomplish this for the past twenty-five years, and we are not discouraged with the result.

Dr. Benjamin H. Shuster, Philadelphia: Dr. McCaskey's talk and the discussions of Dr. Beck and Dr. Kelly are of vital importance to otolaryngologists. It will do no good to discuss these topics before a meeting such as this while in hospitals the general surgeon believes that neck surgery belongs to him, the general plastic surgeon believes that rhinoplasty is in his domain and the thoracic surgeon insists that bronchoscopy is his. After such a division of the field, there is little major work left for the otolaryngologist. This problem can best be solved in the teaching schools. Unless graduate schools include in their curriculums all the topics that we as otolaryngologists believe are within our field, there will always be a question of who is to do what, and we shall get nowhere. If the schools teach students to perform certain procedures, they can say, "Our students have been trained to do this work. It is our work, and we should do it." The spectacle of an experienced otolaryngologist throwing up his hands when he is required to do a ligation in the neck or to open an abscess of the brain is not a healthy one. He may call on a younger surgeon whose ability and experience are less than his own to carry out the procedure, just because he believes he is out of his department. I believe we must assert ourselves in this matter and encourage proper training in the procedures associated with our work. Such a policy will get us the proper recognition. Proper training will not require an extra year of general surgery, as Dr. McCaskey suggests. There is too great a tendency toward piling up years of work irrelevant to the training of an otolaryngologist.

Dr. Hayes Martin, New York: Dr. McCaskey has advised that otorhinolaryngologists take over the treatment of all surgical conditions of the neck except for the diseases of the thyroid gland. I wonder whether he has adequately considered all aspects of the problem. So far as the treatment of benign lesions—cysts, abscesses—of the neck are concerned, any surgeon who has a knowledge of the anatomy of the neck may safely handle the problem. Unfortunately, these benign diseases and conditions are not the most important ones, and I refer particularly to cancer. In my opinion, any surgeon who undertakes an operation for cervical tumor should be competent and prepared to perform any radical procedure which may be required. The preoperative differential diagnosis of benign tumor and cancer cannot be sufficiently accurate to justify any lesser attitude. The operations which may be necessary in cases of cervical tumors, no matter how benign the growths appear in the beginning, include such procedures as wide local resection of the tumor down to the deep vessels and nerves of the neck, excision of the submaxillary salivary gland, excision of the parotid gland with dissection of the branches of the facial nerve, complete radical dissection of the neck, resection of the mandible, ligation of the major vessels of the neck and opening of the pharynx. When Dr. McCaskey advises otorhinolaryngologists to take over all surgical treatment of the neck, does he imply that they already have had previous surgical training adequate to carry out surgical procedure of this type? It appears to me that the problem is more involved and complex than the essayist has indicated. I should like to ask whether Dr. McCaskey has ever known of a case in which a surgeon has exposed a presumably benign tumor or cyst only to find an infiltrating cancer, and, lacking courage and experience to continue, has retreated and consoled himself with the alibi that the tumor was inoperable and that no matter what was done the patient would have died anyway. Many such patients later apply to cancer clinics, where the operations have to be performed again, with a greatly lessened chance of cure. In many others the tumor is found to be inoperable after the first inadequate attempt. The surgeon who operates for a cervical tumor should be prepared to do whatever radical procedure may be necessary to cure cancer. If he is not qualified by training and experience to perform such radical operations, he should not attempt surgical treatment of these tumors.

Dr. Carl H. McCaskey, Indianapolis: I thank the discussers for the points they have brought out in this paper. You will note, when you read the paper, that one of my first statements was that a man, to qualify for this kind of surgery, should be well trained in otolaryngology and should have had at least one year's training in general surgery. As for Dr. Kelly's discussion of tonsillectomy, I included my statement as a sort of feeler, for I wanted you to realize that the tonsil is still in the neck. Dr. Martin made a good point when he said that a surgeon does not always know what he will find when he makes a surgical entrance into the neck, even for biopsy; he has some idea, but he is not always certain. Therefore, he should be so well prepared when he starts that he will be able to follow through. In most medical schools, we have been subject to the domination of the surgical department. Until we can be on our own and assume complete control of our own departments, we are not likely to get a chance to do this work.

The Intervertebral Disk Syndrome.—In 1927, Schmorl began his meticulous necropsy studies showing the high incidence (38 per cent) of displacement of the nucleus pulposus into the spongiosa of the vertebral body. Schmorl and Andrae also called attention to the cartilaginous masses found within the spinal canal, consisting of nucleus pulposus herniated through defects in the annulus fibrosus. The modern concept of the syndrome of protrusion of intervertebral disk dates from the work of Mixter and Barr, Adson, Love, Craig, Camp, Walsh, Dandy, and Bradford and Spurling. The first case of intervertebral disk herniation to be described clinically was that of Kocher in 1896. Since 1934 a voluminous literature on the subject has accumulated: The first published report of a patient operated on for protrusion of an intervertebral disk into the spinal canal was that of Oppenheim and Krause in 1909.—Lewin, Philip, M.D., *Journal of the International College of Surgeons*, March-April, 1948.

MANAGEMENT OF TICK TYPHUS (ROCKY MOUNTAIN SPOTTED FEVER) IN CHILDREN

W. M. KELSEY, M.D.
and
G. T. HARRELL, M.D.
Winston-Salem, N. C.

The prevalence, severity and high mortality of tick typhus (table 1) in the Eastern states are not generally appreciated. It is probable that the actual incidence is much higher than the number of cases would suggest. In our series of 27 patients in the pediatric age group there have been 7 deaths, a death rate of 26 per cent. Our series is probably made up largely of cases of unusual severity, since most of the patients were referred to our hospital because their condition was critical. During this same period (1943 to 1946) the national mortality rate for patients less than 39 years of age was 12 per cent. The mortality rate in North Carolina during the past two years was 31 per cent, a figure comparable to ours.

There are two possible explanations of the high death rate in North Carolina. The strain of the organism may be unusually virulent, or the cases reported to the health department may be only the most severe ones.

HISTORY AND PHYSICAL EXAMINATION

One of the biggest problems in the management of tick typhus is the establishment of the diagnosis at an early stage in the disease. The history and physical examination can be of great help in the diagnosis. Only 50 per cent of our patients gave a history of having removed an engorged tick prior to the onset of fever. This fact suggests that the contact with the tick need not be so long nor so intimate as is believed, or that there may be some vector other than the tick. No studies have been made in North Carolina to demonstrate the animals which serve as a reservoir of the disease or other arthropods which might serve as vectors.

Table 1.—*Rocky Mountain Spotted Fever, Cases and Case Mortality*

	1936		1937		1944		1945

North Carolina	32	25	29	17.2	59	32	57	31.7
Total for United States	362	24	429	20	470	27.6	474	....

The incubation period in our patients, when it was known, varied from one to eight days. The prodromal period lasted from one to nine days; in only 4 patients, however, was it more than four days. Three of these patients with long prodromal periods were moderately ill, and 1 was severely ill. High temperature, severe headaches and vomiting were common in this period. During this time the Rumpel-Leede phenomenon may help to suggest the diagnosis.

Read before the Section on Pediatrics at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 12, 1947.

From the Departments of Pediatrics and Internal Medicine of the Bowman Gray School of Medicine of Wake Forest College and the Pediatric Service of the North Carolina Baptist Hospital.

These studies were aided by a grant from the John and Mary R. Markle Foundation.

The rash usually appears first on the extremities, but may spread so rapidly that by the time it is first noted most of the body may be involved. The rash, which is maculopapular, may become petechial and purpuric, and may even progress to gangrene. In our experience the administration of serum early in the disease modified the rash (fig. 1). The severity of the rash is an index of the severity of the disease.

Physical examination usually reveals a dehydrated and seriously ill child. The pulse is rapid, and the blood pressure is at the lower limits of normal. In addition to the rash, there is nearly always demonstrable edema which is generalized, frequently nonpitting, and not dependent (figs. 2 and 3).

LABORATORY STUDIES

Laboratory studies have been of considerable interest. Nearly all of our patients experienced severe anemia (table 2). The loss of blood did not seem sufficient to explain the anemia, and no evidences of hemolysis were noted. Though it has been said[1] that the leukocyte count is usually elevated, the white blood cells during the first seven days of the disease numbered less than 10,000 in 85 per cent of our cases. Later in the disease the white blood cell counts rose above 10,000 in the majority of patients. In many cases it was felt that the leukocytosis was associated with the appearance of secondary bacterial infections or followed hemorrhagic phenomena. The differential count showed an average of 70 per cent polymorphonuclear leukocytes regardless of the total number of white cells. Twenty per cent of the polymorphonuclear leukocytes were nonsegmented.

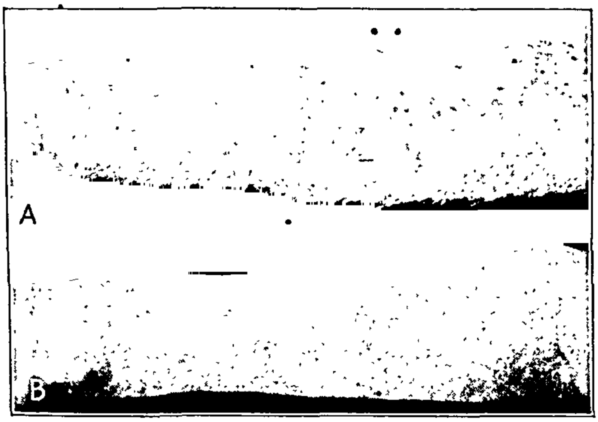

Fig. 1.—*A*, eleventh day of rash in a case of severe disease. Note the hemorrhagic character of the diffuse rash. *B*, tenth day of rash in a case in which serum therapy was used. Note discrete papules.

The microprothrombin time was determined in 5 patients. In 3 of these patients it was normal. One patient, who had a normal prothrombin time on admission, received prophylactic oral doses of vitamin K, 1 mg. daily for five days. At that time the prothrombin time was 2 minutes against a control of 14 seconds; when this test was repeated the prothrombin time was 3 minutes against a control of 18 seconds. After 1 mg. of vitamin K was given parenterally, the time returned to normal and remained so. The fifth patient had a slightly elevated prothrombin time on admission. One day later the prothrombin time was 2 minutes and 30 seconds, in comparison with a control of 19.5 seconds. The prothrombin time remained at this level for five days in spite of the daily parenteral administration of 4 mg. of vitamin K.

The total serum proteins (table 3) tended to be low, and dropped below 5 Gm. per hundred cubic centimeters in 14 patients. The serum albumin fell below the critical edema level of 2.5 Gm. per hundred cubic centimeters in 6 cases (table 3). Blood levels of nonprotein nitrogen and chlorides were determined on admission. Thirty per cent of these patients had nonprotein nitrogen levels above 40 mg. per hundred cubic centimeters. Fifty-five per cent of this group had blood chloride levels below 92 milliequivalents per liter (table 3).

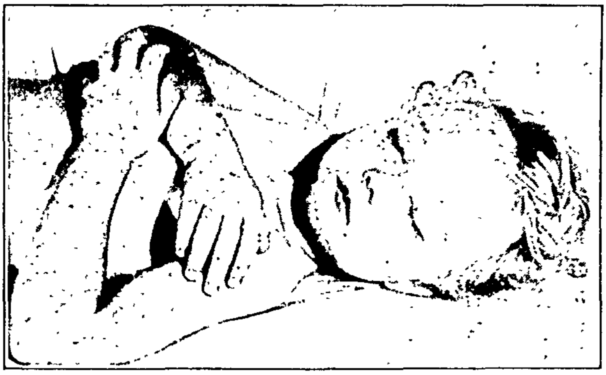

Fig. 2.—Patient M. D. on sixteenth day of rash. Note the pronounced edema with closure of the eyes.

Blood volumes were determined by the "Evans blue" technic[2] and extravascular fluids by the thiocyanate method.[3] The blood volumes tended to be low at the peak of the disease. The large amounts of fluid present in the extravascular spaces, particularly during the edematous stage, corroborated our impression[4] that the loss of fluids from the vascular spaces was even greater than had been expected and supported the hypothesis that this fluid shift is a factor in the production of the peripheral vascular collapse. These studies will be reported at a later date.[4a]

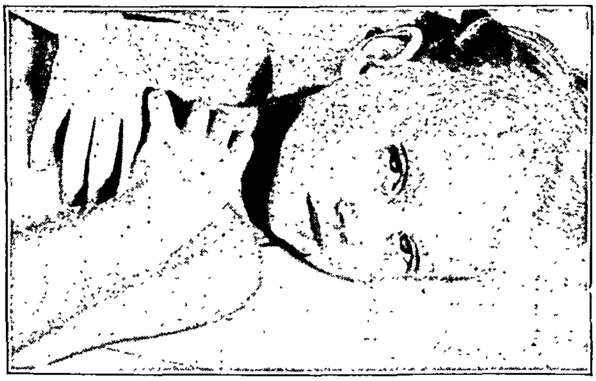

Fig. 3.—Patient M. D. after recovery. Note subsidence of edema.

The cerebrospinal fluid was examined in 8 patients. No abnormalities were noted in 2 cases, and in 2 others the only finding was increased pressure. Three patients showed 11 to 22 mononuclear cells in the spinal fluid as the only evidence of intracranial involvement. In 1 patient the fluid was obtained under increased pressure, and the protein content was elevated. In 1 patient who had two negative spinal fluid examinations there were severe sequelae, manifested by pronounced mental retardation and behavior disorders.

Two serologic tests are of value in confirming the diagnosis of Rocky Mountain spotted fever. A positive reaction to the Weil-Felix test confirms the presence of a rickettsial disease, but does not differentiate clearly between murine typhus and tick typhus. A persistently negative reaction to the Weil-Felix test helps to exclude tick typhus. The complement fixation test is specific for tick typhus. These serologic tests are diagnostic only when the titer rises during the course of the illness. They are of no value early in the disease, since the titer does not reach diagnostic levels before convalescence. The highest titers in our patients were obtained against Proteus OX-19, though in 1 patient who died the OX-2 and OX-K strains gave reactions in higher titer. Three patients had positive complement fixation reactions[5] for murine typhus, though in all of these the titers with tick typhus were higher.

CLINICAL COURSE AND COMPLICATIONS

The clinical course of the disease was fairly constant. There were no deaths in patients who survived more than fourteen days after the onset of fever. The duration varied from eight to twenty-eight days, the average being twenty-one days. We were unable to predict the outcome from the appearance of the patient when first seen. Two critical periods were common: at the time of admission and on the tenth day of the rash. Electrolyte disturbances and shock occurred early in the disease; later, peripheral circulatory collapse and pneumonia were common.

Few diseases have so many complications as tick typhus. Peripheral circulatory collapse is the most common. A rising pulse rate, especially if it goes above 140, is an indication of impending trouble. The appearance of a thready pulse and a drop in the blood pressure are ominous signs. Peripheral circulatory collapse usually occurs when the edema is maximal, although it may take place earlier in the disease if dehydration is severe. It sometimes develops so suddenly that recognition at an early stage is made possible only by frequent and careful examinations. Sixty per cent of our patients, and all of those who died, had circulatory collapse some time during the illness.

Though none of our patients had definite evidence of cardiac failure, this may occur. Any increase in venous pressure, a gallop rhythm or enlargement of the liver should make one suspect that there is severe myocardial involvement. Pneumonia has been a common and severe complication, and it is difficult to differentiate this from cardiac failure. Forty-five per cent of our patients had clinical or pathologic evidence of pneumonia. Pneumonia was thought to be a major factor in 4 of the 7 deaths in our series.

Nearly all the patients had signs of involvement of the central nervous system. Coma, delirium and fine tremors of the hand were common. Neither the clinical findings nor the spinal fluid studies enabled us to predict which children would be left with permanent damage to the nervous system. Fortunately, only 1 patient had any neurologic sequelae.

PATHOLOGY

The pathologic findings in tick typhus have been well described.[6] In our cases the most striking lesions were seen in the myocardium, lungs and brain. Though the heart usually showed mononuclear cell infiltration, there was in no case evidence of cardiac dilatation. Three pathologic lesions were seen in the lungs. Two patients had bronchopneumonia of bacterial origin. In 2 cases extensive mononuclear cell infiltration was seen in the interstitial spaces. One patient had diffuse alveolar and interstitial hemorrhage.

We feel that peripheral circulatory collapse is a frequent cause of death. This collapse is probably due to the shift of fluids from the vascular to the extravascular spaces, with a concomitant decrease in the blood volume. The two mechanisms probably responsible for this shift of fluids are reduction in the colloid fraction of the blood and leakage of fluids through damaged blood vessels. There are several possible explanations for the lowered protein value of the serum.

---

P. S.	3	1.0	1	3	2	20	Recovered
J. R.	14	1.0	1	6	2	17	Serum sickness; recovered

In many cases the patient is so sick that he is unable to maintain an adequate protein intake unless aided by gavage feedings. Indirect evidence suggests that the synthesis of proteins in the liver may be impaired. Small amounts of protein are lost in the urine, and protein may be lost into the tissue spaces through the damaged vascular system. Studies of nitrogen balance indicate that there is a tremendous increase in protein catabolism. Since sodium and potassium are important in determining the partition of fluids in the body spaces, abnormalities in their distribution may be a factor in the fluid shifts in tick typhus.

SPECIFIC THERAPY

Two types of specific therapy are now available: hyperimmune rabbit serum [7] and para-aminobenzoic acid. In our experience, hyperimmune serum [8] has not proved to be of great value, even when given in amounts up to 1 cc. per kilogram of body weight daily for three days. Large doses of serum have not yet been given an adequate trial, however. Nine of our patients received serum within the first three days of the rash (table 4). The rash was probably modified in 5 patients. There was no definite decrease in the duration of the illness, though it was felt that at least 2 patients may have had a less stormy course than would have been expected without the serum. The mortality in the serum-treated group was 25 per cent. Because of the scarcity of the serum in 1944 and 1945, only the sickest patients were treated with it.

The value of para-aminobenzoic acid in tick typhus has not been definitely determined, since only 22 cases of tick typhus treated with the drug have been reported in the literature [9] (table 5). Though it is difficult to evaluate any form of therapy in such a variable disease, it was felt that the drug modified the course of the disease in all the reported cases. A similar modification was noted in cases of louse-borne typhus [10] and scrub typhus [11] treated with para-aminobenzoic acid. The evidence which has accumulated is sufficient to warrant its extensive clinical trial. Experience with laboratory animals [12] and with human patients indicates that the drug does not kill the rickettsias but inhibits growth. One would therefore expect the drug to be most effective if given early in the disease, and animal experimentation bears out this expectation.[13] Probably levels of 30 to 50 mg. per hundred cubic centimeters should be attained in the blood.[9f] Two toxic effects have been noted with high blood levels of para-aminobenzoic acid: The carbon dioxide–combining power may decrease moderately, and leukopenia of a mild degree may occur.

We have treated 3 patients in our hospital and 1 patient in another hospital with para-aminobenzoic acid (table 6). All were treated late in the course of the disease, and were critically ill. Three of the patients died, and the fourth survived after a stormy course. *None of these patients offered a fair trial for the drug.*

SUPPORTIVE THERAPY

Supportive therapy is directed at the prevention of cardiovascular complications and pneumonia and at the maintenance of nutrition. Those patients who were dehydrated at the time of admission and had an elevated nonprotein nitrogen level and a low blood chloride level were given calculated amounts of isotonic solution of sodium chloride intravenously until the urinary flow returned to normal. Those patients who had nitrogen retention but normal blood chloride levels received calculated amounts of 5 per cent dextrose in water intravenously. No more than 20 cc. of fluids per kilogram of body weight was given in any single intravenous injection. When signs of peripheral vascular

collapse were present, concentrated albumin, whole blood, plasma or red blood cells were given, the choice of therapy depending on the total serum proteins, the hematocrit reading and the blood volume; plasma and whole blood were the agents most frequently employed in this situation. If clinical signs suggested cardiac failure, no intravenous fluids were given and the patient was digitalized rapidly.

When there is the slightest evidence of pneumonia, penicillin should be administered in generous amounts. Although some experiments[14] suggest that penicillin may inhibit rickettsial growth, the aim of penicillin therapy in tick typhus is the prevention of bacterial pneumonia. We have the impression that penicillin may have saved a few patients in whom this complication might otherwise have proved fatal.

Every effort should be made to maintain a high protein intake. In some cases as much as 7 Gm. of protein per kilogram per day is needed to keep the patients in positive nitrogen balance. Most children with this disease are unable to take the amount and type of food required to maintain their nutrition, and should receive gavage feedings as soon as they refuse the diet. This procedure tires the patient less than prolonged attempts to feed him, and incidentally saves nursing time. Since the liver may not be able to utilize amino acids, proteins should also be given intravenously, in the form of plasma or whole blood. The patients in our series have left the hospital in good nutritional condition. Six children gained weight during the illness; 7 lost not over 5 per cent of their body weight, and the remainder were discharged weighing the same that they did on admission. None of these patients had clinical or laboratory evidence of edema at the time of discharge.

Table 6.—*Patients with Tick Typhus Treated with Para-Aminobenzoic Acid at the North Carolina Baptist Hospital*

J. R.	14	9	18	..	50 mg. per 100 cc.

COMMENT

Though we have no proof that this vigorous approach to supportive therapy has lowered the mortality rate of tick typhus significantly, we have the impression that several patients recovered who would have died without these supportive measures. The most urgent problem at present is to find a procedure which will permit the diagnosis to be established before the appearance of the rash. Until an early diagnosis is possible, no form of specific therapy can be entirely satisfactory.

SUMMARY AND CONCLUSIONS

The clinical and laboratory findings in 27 children with tick typhus are described.

While treatment with specific hyperimmune rabbit serum and para-aminobenzoic acid did not lower the mortality rate significantly, it is felt that neither of these agents was given an adequate trial.

Vigorous supportive therapy is credited with saving several patients who otherwise would have died. Children maintained on a high intake of proteins and vitamins were discharged in good nutritional status. Until it is possible to establish the diagnosis of tick typhus earlier than at present, supportive therapy in this disease will be necessary.

In North Carolina tick typhus is a serious disease carrying a high mortality rate in children.

ABSTRACT OF DISCUSSION

Dr. David M. Greeley, New York: I am a little more optimistic than Dr. Kelsey is concerning the use of para-aminobenzoic acid, but I agree that, if it is to be effective, it has to be used early. Several careful clinical and metabolic studies have been done on patients suffering from both louse-borne typhus and Rocky Mountain spotted fever. The work by Dr. Kelsey and Dr. Harrell and his group at Winston-Salem and of the Cairo-Egypt unit of the American Typhus Commission has done much to elucidate the alterations which take place in the fluid, electrolyte and nitrogen balances and has helped to explain some of the clinical phenomena. The principal pathologic changes in louse-borne typhus and Rocky Mountain spotted fever are in the endothelial and smooth muscle cells of the smaller blood vessels of skin and subcutaneous tissue. The invasion of these cells by rickettsias result in intervascular thrombi and necrosis of these blood vessels. The permeability of these vessels is increased, and this in turn leads to extravasation of blood into the tissue spaces and accounts for the typical hemorrhagic rash which occurs in both of these diseases. In addition to the formed elements of the blood which are lost in the tissue spaces, fluid, chlorides and plasma proteins are lost, resulting in a situation analogous to that which occurs in patients who have been severely burned. The shift in the chlorides and plasma albumin from the blood to the tissue spaces alters the osmotic pressure relationships and gives rise to edema. There follows a reduction of blood volume with a lowering of the blood pressure and the effective glomerular filtration pressure. The latter, coupled with the tremendous destruction of body protein, gives rise to the prerenal azotemia. The principal cause of death, then, in peripheral vascular collapse is easily explained. For a time, the supportive treatment of Rocky Mountain spotted fever included the use of intravenous fluids; then, after a period, it was felt that such treatment was contraindicated. This belief arose because it had been noted that animals treated with intravenous fluids died more quickly and that patients treated in a similar manner did less well than control groups not treated with intravenous fluids. But in these instances, solutions of dextrose and sodium chloride were used, and it is now clear that such solutions will quickly pass into the tissues, thus intensifying the changes which have been described. However, much can be accomplished in selected cases by the intravenous administration of large amounts of blood plasma, albumin or whole blood, which will tend to raise, or at least prevent, a further drop in the plasma proteins; the blood volume will be increased, the blood pressure will rise and, along with it, the glomerular filtration pressure. As a result, there will be less tendency for the development of peripheral circulatory collapse and nitrogen retention. It has been noted, both in louse-borne typhus and Rocky Mountain spotted fever, that patients so treated do much better than control groups. The nitrogen retention in Rocky Mountain spotted fever is due primarily to the great destruction of body protein. However, if large amounts of protein are given by mouth or by gavage, this loss can be curtailed, and in some instances a positive nitrogen balance can be obtained.

Dr. Charles Armstrong, Washington, D. C.: The name of this disease is Rocky Mountain spotted fever, not tick-borne typhus. If one says tick-borne typhus, one might mean Rocky Mountain spotted fever; one might mean boutonneuse, the Mediterranean type, or if one is speaking of mite-borne typhus, one might mean tsutsugamushi or rickettsial pox. Let's stick to the name Rocky Mountain spotted fever. Nothing will be gained by writing tick-borne typhus and then Rocky Mountain spotted fever in parentheses. These patients were seen after the rash first appeared. That is really the first definite diagnostic symptom. But if one waits until the appearance of the rash, one is not seeing the case or making a diagnosis early.

---

[14] Moragues, V.; Pinkerton, H., and Greiff, D.: Therapeutic Effectiveness of Penicillin in Experimental Murine Typhus Infection in dba Mice, J. Exper. Med. 79: 431-437 (April) 1944.

I think that something can be gained by a carefully taken history; a history of a bite with engorgement of the tick about seven to twelve days prior to the onset of the symptoms may give an inkling of what to expect before the appearance of the rash. And then one should, if one suspects Rocky Mountain spotted fever, get serum available so that one can start specific treatment, at the first appearance of the rash. It might be well also to remember that there is an effective vaccination available against this disease, which may be used in especially exposed persons. In Montana, the incidence of the disease has dropped until in 1945 there were but 2 cases reported. This year, there has not been a single case of the disease reported in the state. These results are, I think, largely due to the widespread use of the vaccine in that part of the country.

Dr. Weston M. Kelsey, Winston-Salem, N. C.: I believe that the name tick typhus is better than Rocky Mountain spotted fever for several reasons. Many practitioners have been misled in the diagnosis since they feel that it is a geographically limited disease. Unsatisfactory as it is, tick typhus correlates the vector with the disease as do the names murine typhus and louse-borne typhus. I admit that the terminology is unsatisfactory. The big problem is prophylaxis, especially in the pediatric age group where ticks are not recognized and removed before they have become attached. The question of just how to approach the public health problem in a rural area, such as North Carolina, remains unanswered. It has been difficult instituting programs for routine immunization, not to mention immunization against tick typhus, which would require contact with the patients every year.

THE MEANING OF CANCER RESEARCH

R. R. SPENCER, M.D.
Washington, D. C.

While the human body is a beautifully organized, well governed society of cells, probably no living species is a victim of more disorders and maladjustments than man. From study of the behavior of the various disorders much has been learned about the orderly, normal behavior of living units, i. e., cells, organs and systems. So far as communicable diseases are concerned, it is now axiomatic that they are manifestations of cellular reactions to external parasitic organisms (bacteria, protozoa or viruses). The reactions show a process of adaptation between two living variables, the mammalian cell host and the invasive parasitic agent. This process is essentially a struggle for survival, and it may end in the death of the host, the death of the parasite, the death of both or a compromise through which host and parasite manage to live together satisfactorily. Basically, the cancer process is no exception. It, too, is a movement toward the goal of all living things, survival.

That cancer is essentially the result of a process of cellular adaptation is suggested by the gradual, steplike change in the behavior of cells when they are transformed into the neoplastic stage. Under some conditions, but not all, cancer cells are tougher and have greater survival value than the homologous normal cells.[1] It is also commonly observed that cancer in the terminal stages of the disease will continue to increase in weight, while the rest of the body is wasting away. In experiments with animal transplantation, cancer implants are seen to elicit a richer supply of blood vessels from the host than implants of normal tissues, and they are also seen to assume a rate of multiplication superior to that of the surrounding normal tissue.[2]

Under the influence of the brilliant researches of the last seventy-five years, which have revealed that many human diseases are due to a single invasive parasite, investigators were misled in their search for a single cause of cancer. Not one of the numerous descriptions of parasites as the cause of cancer has withstood the test of time.

What is the status of present knowledge of the carcinogenic process? Cancer research has reached the stage at which the following affirmations can be safely made:

1. The inciting causes of cancer are multiple and complex. In fact, cancers now may be induced experimentally at will by (*a*) genetic manipulations, i. e., inbreeding, selecting and cross breeding; (*b*) injection or feeding of any of several hundred chemicals, some of which are organ specific; (*c*) hormonal imbalances and disturbances; (*d*) many of the energy agents (roentgen rays, gamma rays of radium and ultraviolet rays), *especially in animals that are subjected to interval* exposure to these agents, and (*e*) a combination of two or more of the aforementioned factors. Recently, Copeland and Salmon,[3] of the Alabama Polytechnic Institute, reported cancer in rats due to a simple dietary (choline) deficiency. It seems unmistakably clear that no single specific agent or condition or any single combination of agents or conditions is responsible for the initiation of all types of cancer.

2. Mammalian cancer cells are derived from normal cells. Pathologists without exception now agree on this point.

3. Certain precancerous conditions (warts, moles, papillomas and leukoplakia) are recognized, and no sharp line of demarcation can be drawn between the precancerous and the cancerous process. In contrast, there is no preinfectious process among the communicable diseases.

4. Cancer cells are not supplied with nerves from the host, although they elicit from the host an abundant blood supply and a supporting stroma of connective tissue. This property has been taken as additional evidence of *the autonomous nature of cancer*.

5. A greater variety of species is subject to the carcinogenic process than to any other disease. Spontaneous cancers have been described in insects, birds, fish, reptiles and amphibians, as well as in man, mice, rats, rabbits, dogs, cats, cattle, hogs, sheep and many other mammals. Yet each cancer is species specific. Cancer cells, like normal cells, cannot be implanted successfully in a foreign species except under highly artificial conditions.

6. Cancer reveals itself as a special type of cell behavior, peculiar to *organized multicellular forms*. A cancer is a group of disorganized cells. Every biologist who has observed the marvelous processes of cell differentiation and organization in any developing multicellular embryo wonders not that there is occasional evidence of disorganization, but that there is not more of it.

7. Cancer is not, as often stated, a "universal cell potentiality" because what is now called cancer cannot manifest itself in a single cell species. While free-living

single cell organisms are considered potentially immortal, as long as the environment is favorable and there is an adequate food supply, the life span of all multicellular individual organisms is definitely limited, even under the most favorable conditions. Continuity of life is maintained in multicellular forms through sexual reproduction. Death and extinction seem the penalties for the privileges and advantages of organized multicellularity. To put it another way, multicellularity seems to carry the seeds of its own destruction. A biologist would not claim this is true of all organized systems; but it is suggestive, and I know of no multicellular living thing that lasts forever.

Some investigators think the cancer process is related to the aging process, which may be defined as a gradual and, at present, an apparently inevitable process of disorganization and disintegration. Yet the disorganized cells known as cancer resemble, in many respects, youthful, embryonic tissue rather than cells that are old.

DEFINITION OF CANCER

It is difficult to define the cancer process. Can it be defined as an abnormal type of growth that serves no useful purpose? No, it cannot, because the body possesses many vestiges, as well as numerous moles, warts and benign growths, which serve no useful function. These structures and lesions are not cancers. Is autonomous, unlimited growth characteristic of cancer? No, it is not, because normal cells display unlimited growth when cultivated artificially in flasks and provided with an ample food supply. They do not produce cancers when again implanted in the animal body. Are the invasion and destruction of other tissues peculiar to the cancer process? Not at all. Normal leukocytes invade other tissues, and the so-called trophoblasts in the early stages of pregnancy invade and erode the body of the uterus. Is the ability to spread to other parts of the body and form metastatic tumors a characteristic quality of cancer? Certain tumors, such as the basal cell carcinoma of the skin and the tumors of the brain, do not metastasize. They are none the less malignant. Thus, it is not possible to pigeonhole cancer or to choose any one quality peculiar to the cancer cell.

When one attempts to summarize present knowledge of the carcinogenic process, one finds that much has been learned concerning what the late Dr. James Ewing called "the causal genesis" of cancer, i. e., the multiple external and internal environmental agents and conditions that start the carcinogenic process but are not essential thereafter to its continuation. On the other hand, little has been learned about the nature of the permanent intracellular change that takes place when normal cells are transformed into cancer cells, or what Ewing termed the "formal genesis." Many theories have been advanced to explain this intracellular change. It has been ascribed to the stimulating effect of latent intracellular viruses activated by the various inciting environmental factors mentioned previously, to the "hybridization" of an intracellular virus and the mammalian cell, to somatic mutations, to altered enzyme patterns and to modified mitochondria. But, regardless of the known inciting factors in the "causal genesis," and regardless of the various theoretic explanations of the "formal genesis," in every case of cancer the end result is essentially the same. Cancer is a process in which certain cells of an organized cell group have become parasitic on and finally fatal to the mother organism. These cells are truly traitors from within, in contrast to those responsible for the communicable diseases, which are all invasive gangster cells (bacteria, protozoa, viruses) from without. If cells become parasitic solely because they are activated by latent intracellular viruses, as some believe, it is necessary to postulate the existence of almost as many viruses as species and individual organisms, since each spontaneous cancer is species specific and largely individually specific. The phrase "individually specific" means that a spontaneous cancer arising in an individual organism of any species cannot be transplanted successfully, as a rule, to other individual organisms of the same species, unless one is dealing with highly inbred strains of animals, the members of which are as nearly alike as identical twins.

Although I hesitate to introduce new terms, one may think of cancer as an "autoparasite," in order to set it apart from the communicable diseases caused by external parasites. Perhaps the term "autosite" contrasts better with "parasite," but "autosite" has already been applied to the independent member of parasitic twin monstrosities. It is interesting that some cancers do possess characteristics which can be thought of as belonging to a latent parasitic twin, the production of which is without question an abnormality of the developmental process.

In attempting to classify cancers or to describe adequately the cancer process, one must remember there are no complete dichotomies anywhere in biology, but, rather, that there exists an almost imperceptible gradation in form and function, from the most primitive of organisms to the most complex.

UNIQUE QUALITIES OF CANCER

No two cancers seem identical in either causation or behavior. The parts played by heredity, by hormones, by diet, by external environmental conditions are seldom the same in cancers of different organs. The well known coal tar product methylcholanthrene seems to induce a cancer in practically any mammalian tissue in which pellets of this insoluble hydrocarbon are placed. On the other hand, among the several hundred chemicals which induce cancer when injected into or fed to animals, another coal tar product (beta-naphthylamine) when given to dogs causes cancer of the bladder only.

The azo dyes will induce cancers of the liver only when fed to rats and mice and compounds of relatively simple chemical structure (chloroform and carbon tetrachloride) also induce cancer of the liver, but not of other tissues.

An alkaloid (contained in ergot)[4] fed to rabbits for two years caused neurofibromas on the ears only. Tumors of the kidney followed the injection of a synthetic organic chemical (beta-anthraquinoline).[5] Urethane,[6] another synthetic organic compound, caused an increase in incidence of spontaneous tumors of the lung in a certain strain of mice, from less than 5 per cent to more than 75 per cent. Interestingly, the same drug has been used with good results temporarily in the treatment of human leukemia.[7]

Gordon[8] showed that the spotted platyfish (Platypoecilus maculatus) when mated to a member of its own species produces spotted but perfectly normal young. A swordtail (Xiphophorus hellerii) mated to a swordtail also produces normal young. But, when a perfectly healthy black-spotted platyfish is mated to an equally healthy Mexican swordtail, hybrid fish are born in which melanotic tumors invariably appear. If an unspotted platyfish is used in a hybrid mating, the disease will not appear. The spotted condition in the platyfish is inherited from one generation to another with a definite mathematic precision.

Sharrer[9] observed that in the insect Leucophaea maderae the removal or injury of the recurrent nerve from the frontal ganglion of the sympathetic nervous system caused tumors to grow in the organs supplied by this nerve. The disturbance of endocrine balance as a factor was ruled out. The insects with tumors died in ten days to several months. Death was apparently due to starvation from obstruction of the alimentary canal.

Little and his group[10] at the Jackson Memorial Laboratory, Bar Harbor, Maine, showed that in 100 per cent of a series of castrated newborn mice (male and female) of a certain strain cancers of the adrenal gland developed after the age of 13 months. Yet the same operation has been employed by Huggins of the University of Chicago,[11] in the treatment of cancer of the prostate in old men. Of 20 patients, in each of whom the cancer had spread to other parts, 18 showed improvement and 4 remained completely free from symptoms for five years after the operation. It is not likely that castration would be helpful in the treatment of all forms of cancer, but why did some of these patients with prostatic cancer respond so favorably and others did not? At present no one knows, but the results suggest there is no "cure-all" and that each cancer is a law unto itself, and differs from all others, even those arising in the same tissue.

Among patients at Veterans Administration Facility, Hines, Ill., Shrek[12] observed that the incidence of cancer of the skin in white men is nearly seven times as great as in Negro patients. The records obtained among veterans also support the observation of many investigators that cancer of the skin in the white race occurs in the southern states much more frequently than in northern states.

The effects of the nutritional factors involved in the origin of experimental cancer are so variable that it seems impossible at present to form any general conclusions. However, Tannenbaum,[13] of Michael Reese Hospital, Chicago, reported that statistics obtained from life insurance companies suggested that among persons who were overweight at the time of the issuance of the policy there was a greater proportion of deaths from cancer than among persons who were of average weight or underweight. Tannenbaum also showed that in experimental animals a restricted diet will reduce the incidence of many different types of spontaneously occurring tumors, including leukemias. These observations provide leads, at least, toward methods of prevention.

CANCER RESEARCH AS AN ACTIVATOR

In my opinion, all the observations on the biology of cancer which have been slowly and painstakingly acquired during the past three or four decades, largely by the efforts of organized groups or what has been termed "interdisciplinary research," set cancer apart from other forms of so-called biologic maladjustments. Cancers and the neoplastic conditions cannot logically be classified with any other group of diseases. Investigators are finding that the problem of cancer is unique in many ways. The acceleration of cancer research since the late war has been due not only to generous federal and private financial support, but also to the fact that the cancer process, involving as it does problems in cell division, in metabolism, in regeneration and in the differentiation and organization of tissues, is of deep interest to all workers in experimental biology and medicine. No other disease problem has created such widespread interest among nonmedical investigators.

Thus, cancer research is activating numerous other fields of biology, and herein lies, I think, its basic importance and its true meaning. The group of fifteen distinguished experts appointed by the Division of Medical Sciences of the National Research Council for the American Cancer Society, whose duty is to recommend the allocation of funds for cancer research, is significantly called the "Committee on Growth." This designation recognizes that the cancer process is basically a problem in growth, and a study of growth leads naturally into practically every field of biology.

The extent to which the funds for the study of cancer are now supporting research in fundamental disciplines may be realized simply from a listing of the panels and sections set up by this committee. In the section on biology are panels on botany, cellular physiology, human genetics, experimental genetics, morphogenesis and viruses. In the section on chemistry are panels on cytochemistry, enzymes, experimental endocrine physiology, nutrition, proteins and synthesis and metabolism of steroids. In the section on chemotherapy are panels on bioassay, chemical-biologic coordination and the mechanism of action. There are two other sections, on clinical investigations and physics, with appropriate panels. Thus, the problem of cancer has stimulated research in many fundamental sciences.

THE POSSIBLE YIELD OF CANCER RESEARCH

In the history of science, time after time experiments designed to solve a specific problem have yielded unexpected, and sometimes highly significant, results. I am certain such results will mark the expanding program in cancer research. I trust a reference to a personal experience which illustrates this principle in a small way will be forgiven. Some years ago my associates and I began to study the effect of cancer-inducing agents on free-living, single cell species, exposing them continuously for long periods covering many generations.[14] It was believed that permanent morphologic changes might gradually be produced. Such changes were not obtained, but these studies gave information which subsequently enabled us to establish through reproducible experiments three principles involved in the mechanism of cellular adaptation to unfavorable environments. We found that continuous exposure to conditions which were apparently harmless to individual organisms and cultures would be fatal in time to the species. On the other hand, a discontinuous and alternating exposure to the same conditions resulted in survival and adaptation. Lastly, we observed that the ability of organisms to resist unfavorable environments was a function of their age or maturity. Unexpectedly, these experiments gave a better insight into the mechanisms by which living organisms survive or adapt to unfavorable environments. It is certain that the survival of the single cell, the multicellular organism and the species is never coextensive, and, therefore, one must always hold in mind that what may be to the best interest of an individual is not necessarily to the best interest of the race or species, Race preservation, rather than self preservation, may be the first law of nature.

The release of atomic energy and the development of the atom bomb has deepened the faith of people the world over in the power of science. Indeed, these achievements have caused many to expect from biologic science too much, too soon. However, in the course of a few decades, and when a large number of talented young men and women can be recruited into the ranks of biologic research, I believe that the generous support of the public for cancer research will be justified in the results—perhaps in the by-products alone. The potentialities of new observations are not always realized.

I think I can speak for many investigators, though perhaps not all, in saying that the scientific method is more than just a working method and a means to an end. *I am sure that many scientists hold these truths* to be self evident:

1. The scientific method is the most effective tool man has ever devised for cutting into the facts of life and uncovering the secrets of nature.
2. The scientific method is a discipline and a way of life—the only way of life that has received universal approval.
3. Science is the only trustworthy custodian of truth in the world today.

IDENTIFICATION OF MALIGNANT TISSUES

HARRY S. N. GREENE, M.D.
New Haven, Conn.

A problem of considerable importance in practical pathology, as well as in cancer research, is the identification and classification of malignant tissues. The characterization of tissues as malignant or cancerous derives from a biologic conception of these states; yet in most laboratories of pathology the distinction is based solely on morphologic considerations. Thus, the assessment of properties and potentialities becomes an interpretation of fixed appearance, rather than a judgment based on actual behavior.

Morphology indicates character, but the proof of malignancy lies in behavior. Many tissues and tissue states bear a remarkable resemblance to cancer, but their fate in the organism and their significance to it place them in entirely different categories. Early embryonic tissues frequently resemble cancer so closely that the distinction cannot be made on the basis of a histologic examination of a section, and the definition depends on the fact that in the primary host and in experimental animals, embryonic tissues undergo differentiation while cancerous tissues do not. In like manner, the morphologic characteristics of productive inflammatory foci or of exuberant granulation tissue may lead to a diagnosis of sarcoma. Yet removal of the stimulus restrains proliferation and controls the lesion.

By far the more important group, however, are the neoplastic lesions representing developmental stages of cancer rather than the fully evolved autonomous growth capable of invasion and metastasis. Cancer is not the result of a sudden transformation of normal cells but, on the contrary, represents the final stage in a developmental process. The various stages of this process cannot be distinguished from their product with any degree of consistency on purely morphologic grounds, but the difference in biologic behavior is always of a major order. This difference is evident to the clinician who observes recovery of a patient after the surgical removal of a lesion diagnosed as cancer by the pathologist or who follows a patient with a morphologic diagnosis of cancer for years before metastasis occurs. The surgical pathologist's opinion in such cases is, of course, not a diagnosis at all, but a prognosis.

The distinction between cancer and its developmental stages or other morphologically similar tissue states is particularly evident to the biologist who studies the reactions of the tissues to transplantation. The reactions to transplantation of several of the commoner tissues are shown in the table. It will be noted that only embryonic tissue and cancer tissue survive heterologous transfer. The heterotransplantability of embryonic and cancer tissues accents their biologic relation. This observation is of considerable interest in itself; but for present and practical purposes, it is important to note only that reactions to transplantability constitute a biologic test for cancer. If the tissue in question grows in an animal of alien species, it is either embryonic tissue or cancer, and, even with present knowledge of gross pathology, the surgeon ought to be able to manage this phase of the distinction.

Heterologous transfer offers a basis for the biologic diagnosis of cancer and is also of value in the classification of tumors. A laboratory report describing a metastatic tumor as disorganized and anaplastic is of little use to the clinician in his search for the primary site, but such a report interprets the microscopic picture and represents the limitations of present technics in surgical pathology. Fortunately, the growth of such tumors in lower animals is associated with a higher degree of cellular differentiation and structural organization than that present in the parent cancer, and study of the transplants allows a more precise classification than is warranted from the morphologic features of the biopsy specimen.

The technic of heterologous transfer is extremely simple. The anterior chamber of the eye is used as a transplantation site, and the guinea pig is the animal of choice. After application of a 5 per cent aqueous solution of cocaine to induce anesthesia, the chamber is opened close to the upper border of the corneoscleral junction by means of a short, quick jab with a double-edged corneal knife. A small amount of fluid is allowed to escape, and a fragment of tumor measuring approximately 0.5 mm. in diameter is introduced into the chamber. Insertion of the tumor fragment is facilitated by the use of a trocar provided with a tight-fitting plunger and a short-beveled extremity. The fragment is then forced into the inferior angle of the iris by applying light pressure with a blunt instrument along the corneal surface. The corneal incision is not closed.

It is essential that judgment be employed in selecting fragments for transfer, for growth cannot be expected if necrotic material or scirrhous tissue representing desmoplastic reaction is used. Examination of frozen

Read in a Symposium on the Present Status of Cancer Research before the Section on Pathology and Physiology at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June *13, 1947.*

sections is often helpful in locating desirable portions of the specimen. It should be emphasized that only cancer tissue will survive heterologous transplantation. Benign tumors and so-called precancerous lesions fail to grow and rapidly disintegrate or undergo hyalinization.

The tissue need not be transplanted immediately after operation, for it will survive at ice box temperature for several days. It is possible, therefore, to preserve representative fragments in sterile Petri dishes, until routinely fixed sections have been prepared and examination suggests the desirability of further study.

The guinea pigs are not subjected to special treatment before or after transfer, but they are maintained under ordinary conditions of cage life. Neither their age nor sex appears to influence the incidence of takes or the course of growth.

Transplantation Reaction

	Type of Transfer		
Type of Tissue	Autologous	Homologous	Heterologous
Normal adult	+	+	−
Normal embryonic	+	+	+
Benign tumor and developmental stages of cancer	+	−	−
Cancer	+	+	+

The following cases are cited as illustrations of the use of this technic for purposes of tumor classification.

A woman aged 45, with a greatly enlarged inguinal lymph node, presented herself for examination. The remainder of the physical examination and the history as obtained from the patient at the time were not contributory. The node was removed, and histologic examination showed scattered anaplastic cells, with a preponderance of necrosis and desmoplastic reaction. There was nothing to indicate the proper classification or the primary site. Fragments of the mass were transferred to guinea pigs, and, when several of them were killed twenty days thereafter, the anterior chambers were observed to be approximately half filled with growing tumor. On section, the transplants were shown to consist of vascularized masses of cells with such characteristics of structure and organization that a histologic diagnosis of a melanotic melanoma was readily made. The patient was reexamined, and on direct question she told of the removal of a nevus from the foot several years previously.

A man aged 35 entered the hospital with a tumor of the sixth cervical vertebra, diagnosed elsewhere as osteogenic sarcoma. Biopsy specimen was taken, and on examination of a frozen section no diagnosis other than anaplastic tumor and necrosis could be made. Accordingly, fragments of the specimen were transferred to the eyes of a number of guinea pigs. The following day, a thorough search of paraffin sections disclosed several areas of greater cellularity than was noted in frozen sections, but these were nondescript and without indicative organization. A guinea pig was killed ten days after transfer, and the histologic structure of the growing transplant was typically that of a chordoma. It is of interest and in keeping with the results of transfer that the tumor metastasized and the man died a short time after operation—a relatively rare termination of growths of this type.

A woman aged 24 entered the hospital with recurrent tumor three years after incomplete removal of a growth from the eighth thoracic vertebra. The growth had been diagnosed as hemangioblastoma, and review of the sections revealed the classic histologic picture of such a tumor. At the second laminectomy, the tumor tissue showed a more disorganized structure, but the general appearance was consistent with the anaplastic development of a hemangioblastoma, and such a diagnosis was made. However, when the guinea pigs bearing grafts of the tumor were killed, twelve days after transfer, the transplants showed a well organized growth of cells whose *structure and arrangement were typically those of a chondrosarcoma.* As might be expected, considerable doubt was expressed by the clinicians as to the validity of the revised diagnosis; but at autopsy, approximately a year later, the typical chondrosarcomatous histology of an intrathoracic extension and of the widespread metastases attested the reliability of the guinea pig test.

A further use of heterologous transplantation as a means of determining the true nature of tumors of uncertain origin is *exemplified by a case of a boy with so-called myxosarcoma of* the hypopharynx. Considerable uncertainty has always existed as to the origin of this type of tumor, the question being whether it actually represents a malignant growth of myxoid tissue or whether it is merely a fibrosarcoma undergoing myxoid degeneration. An unmistakable answer was given by the guinea pig inoculation, at least for the case under discussion. In this instance the tissue used for transfer was the histologic prototype of myxosarcoma, yet the morphologic character of *the growing transplant was manifestly that of a fibrosarcoma.*

CONCLUSION

The object of this report is to call attention to the value of heterologous transplants as an aid to the diagnosis and classification of human tumors. The ability to survive in an alien host is not shared by normal adult tissue, benign tumors or chronic granulomas, and the mere fact of growth immediately identifies the tumor in question as cancer. The value of the procedure is enhanced from a diagnostic point of view by the increased differentiation and organization exhibited in the growing transplant. Completely disorganized tumors often undergo alterations in stromal-parenchymal relations to reveal an organized structure indicating the tissue or organ of origin. In other instances, an increased differentiation of the transplanted cells betrays their proper classification.

Laboratory of Pathology, Yale University School of Medicine.

ABSTRACT OF DISCUSSION

Dr. Stanley P. Reimann, Philadelphia: Dr. Greene has shown that the addition of his particular test helps greatly in the classification of tumors. A morphologic statement is not a finished diagnosis; but Dr. Greene, I am sure, will agree that those who use his method must first have had some experience and training in pathologic anatomy. The name given to a tumor makes no difference to the patient, nor does he care how it behaved in himself or in the guinea pig's eyes. The patient's fate depends on whether or not every last cancer cell has been removed or destroyed. But the study of the behavior of tumors is of the utmost importance to an understanding of malignancy. I again call your attention to the "confusion of tongues" in regard to tumors. Differences in words are often taken to mean differences in things and in phenomena. Something should be done about it! I still recommend that pathologic anatomy be taught first and then as much of the behavior of tissue as is known. But one must continuously bear in mind the difference between the patient's point of view and the position that the study of cellular activities in all their phases will eventually lead to a better understanding of cancer. Perhaps the patient, in the indefinite future, will also come to a different point of view.

Dr. E. V. Cowdry, St. Louis: I should like to ask about the essential feature, the failure of normal and chronic granulomatous tissues to grow, whereas malignant and embryonic tissues are capable of growth. In the transplantation of embryonic tissue, does the ability to grow fade out at the same time in the different types of cells? Does it stop suddenly, or does it gradually cease?

Dr. R. R. Spencer, Washington, D. C.: Dr. Greene's paper represents splendid pioneer work; as time goes on it will be increasingly important. However, I am skeptical about his classification and the attempt to "pigeonhole" cancer. I believe cancer is a process that is so general that it is difficult to classify. For this reason, I understand that leukemias, which certainly belong in the class of malignant hyperplasia and the malignant process, are excluded by Dr. Greene because leukemia cells will not grow by his method. I also understand that there is at least one experimental tumor in the rat—that developed by Dr. W. F. Dunning in her laboratory in the Detroit Institute of Cancer Research, which develops and kills the animals but which does not grow in the anterior chamber of the eye of heterologous species.

Dr. Alvin G. Foord, Pasadena, Calif.: If one took 100 consecutive malignant tumors and implanted each one in an animal, how many positive takes would result?

Dr. Robert S. Stone, San Francisco: One of the advantages of a conference is that one can hear the other man's discussion. I am a radiologist. It has always annoyed me that the pathologist notes a tumor as either radiosensitive or radioresistant, thereby encouraging, or discouraging, the clinician's advocation of treatment. Dr. Greene has shown a beautiful example of the difficulty one may have in telling from one section whether a tumor may be radiosensitive or radioresistant. Moreover, I should like to point out that labeling a tumor as radiosensitive or radioresistant has nothing to do with its curability. A most radioresistant tumor, such as cancer of the lip, may be the only one that can be cured, whereas a lymphoma or such a radiosensitive tumor as was shown a few minutes ago is seldom curable. In this respect, I differ with Dr. Reimann that one can make a prognosis, because with tumors that grow like the one shown here it is seldom possible for the surgeon to remove all the growth, for it has already gone too far. It is almost impossible for the radiologist to bring about a cure because, as Dr. Greene showed, the growth in the treated region disappeared beautifully but the tumor was already somewhere else. I hope that these studies of Dr. Greene's will result in a means, by behavior technic, of telling more of a practical nature about what radiologists should do with tumors.

Dr. Harry S. N. Greene, New Haven, Conn.: Dr. Reimann asked how frequently I believe a diagnosis of cancer could be made microscopically. The answer, of course, depends on one's definition of cancer. If cancer is defined in purely morphologic terms as a growth showing alterations in the size, shape and staining qualities of cells and nuclei; loss of polarity, and an increase in the number of mitoses, then a microscopic diagnosis can always be made. If, on the other hand, one's conception of cancer derives from its biologic attributes, and such properties as autonomy and ability to metastasize are considered as essential identifying qualities, then the basis of diagnosis depends on behavior. The technic I have described is a method of assessing character through behavior, and in my experience it has proved more reliable than the microscopic method of judging character from appearance. Dr. Cowdry's question concerned the growth of embryonic tissue in the anterior chamber of the guinea pig eye and how it differs from the growth of cancer. Cancer grows progressively and can be transferred serially through unlimited generations of animals. Embryonic tissue, however, undergoes differentiation after a period of rapid proliferation; subsequent growth is slow, and serial transplantability is limited to several generations. This distinction requires comment in passing. Actually, it is the most conspicuous difference between the two tissues. Morphologically, immunologically and biochemically cancer tissue and early embryonic tissue are identical. However, both in the primary host and in the experimental animal, embryonic tissue undergoes differentiation, whereas cancer tissue does not. It would appear, therefore, that the step from embryonic tissue to cancer was a relatively short one and that it was concerned with the process of differentiation. Accordingly, one of my endeavors has been to modify or to inhibit the differentiation of embryonic tissue, with the hope of producing a cancer. Briefly, it has been observed that if a crystal of methylcholanthrene or other so-called carcinogenic hydrocarbon is added to the embryonic organ at the time of transfer, a carcinoma characteristic of the transplanted tissue develops within thirty days.

Dr. E. V. Cowdry, St. Louis: My question was: When does the failure to grow appear in embryonic tissues? Does it appear suddenly in tissues of many kinds at the same time?

Dr. Harry S. N. Greene, New Haven, Conn.: Dr. Cowdry asked at what age embryonic tissue loses the ability to survive heterologous transfer. The age differs according to species. In man heterotransplantability is lost during the fifth month of gestation. It is retained throughout the greater part of embryonic life in the mouse, ceases at about the twenty-fifth day in the rabbit and about halfway through gestation in the guinea pig. A question was asked concerning the heterotransplantability of the lymphomas. Despite numerous attempts, I have not been able to transfer leukemia, Hodgkin's disease or any of the other lymphomas from man to lower animals. The inability to grow on transplantation would seem to constitute further evidence against their classification as neoplastic diseases. A question was asked concerning the percentage of takes to be expected from the transplantation of a human cancer. The number of takes is directly proportional to the amount of stroma or desmoplastic tissue present in the tumor. Stroma and desmoplastic tissue are adult tissues and they excite a foreign body reaction in the alien host, which may completely destroy the transplant. Successful transfer depends on the selection of tumor fragments containing a preponderance of parenchyma, and such selection is easily made from the appearance of frozen sections.

CANCER OF THE HEAD AND NECK

HAYES MARTIN, M.D.
Attending Surgeon, Memorial Hospital
New York

(Continued from p. 1314 in The Journal, Aug. 7)

III. CANCER OF THE LARYNX

Anatomically the larynx extends from the tip of the epiglottis to the inferior margin of the cricoid cartilage, and the term cancer of the larynx, therefore, includes all malignant growths arising in the epiglottis, the aryepiglottic folds, the arytenoids, the ventricular bands, the ventricles, the vocal cords, the subglottic area and the postcricoid region. Laryngeal cancer may be divided anatomically into two general groups: (1) Growths arising on the vocal cords and ventricles and in the subglottic region are classified as cancer of the intrinsic larynx, and (2) growths arising on the upper surface of the ventricular bands, the epiglottis or its appendages or in the postcricoid region constitute cancer of the extrinsic larynx.

ETIOLOGY

Laryngeal cancer comprises about 2 per cent of all human malignant tumors. Like cancer of the mouth this disease occurs most often in middle and old age, and predominantly in males (97 per cent). The incidence of intrinsic and extrinsic laryngeal cancer is about equal.

Causative Factors.—The preexistence of chronic local irritation which may so often be shown to play a part in the causation of malignant growths of the oral cavity is not readily demonstrated in cancer of the larynx. Although excessive smoking with inhaling, voice strain and syphilis are undoubtedly etiologic factors in an occasional case, these forms of irritation cannot be shown to have a significant etiologic role in most cases of laryngeal cancer. The disease usually appears to arise spontaneously. Leukoplakia of the larynx (pachyderma laryngis) sometimes undergoes malignant transformation.

PATHOLOGY

Epidermoid or squamous carcinoma is the predominant histologic form of cancer which affects the larynx. This is to be expected in a mucosa which consists entirely of stratified squamous epithelium covering the vocal cords and a pseudostratified transitional type lining the larynx above and below the cords. In the intrinsic part of the larynx, over two thirds of the growths are well differentiated epidermoid carcinoma (grades 1 and 2) and in the extrinsic part of the larynx about 50 per cent fall into this class. The degree of anaplasia of laryngeal cancer generally increases the further its site of origin is removed from the region of the cords.

SYMPTOMS, MORBID ANATOMY AND CLINICAL COURSE

The symptoms of laryngeal growths vary greatly depending on the exact site of origin.

Cancer of the Intrinsic Larynx.—Hoarseness is invariably present in the early stages of cancer of the cords, and in practically all cases careful questioning of the patient will reveal that this was actually the first symptom. The progress of the disease is usually slow, and hoarseness may persist as the only symptom for as long as one to three years in untreated patients before the airway is diminished sufficiently to produce dyspnea. As the disease infiltrates deeply into the vocal cords, complete aphonia results. If, on the other hand, the lesion tends to fungate rather than to infiltrate, husky phonation may be accompanied by gradually increasing dyspnea as the aperture of the glottis is narrowed. Eventually, the disease may perforate the laryngeal cartilage or the cricothyroid membrane to invade the soft tissues of the neck. Metastasis to the cervical lymph nodes rarely occurs early in the course of this anatomic variety of laryngeal cancer.

As viewed through a throat mirror or laryngoscope, early cancer of the intrinsic larynx usually appears as a granular, papillary outgrowth or as a flat, slightly excavated ulcer with raised borders, most frequently situated in the free edge or upper surface of the anterior two thirds of the vocal cords (fig. 9). The posterior third of the cords or the posterior commissure is seldom the primary site of origin. In later stages the growth infiltrates more deeply with eventual fixation of the affected cord, and as the disease progresses the lesion spreads upward into the ventricle and the ventricular band and across the anterior commissure to involve the opposite cord. Characteristically, cancer of the intrinsic larynx remains a fairly well localized disease until death.

Cancer of the Extrinsic Larynx.—The symptoms of extrinsic laryngeal cancer are varied and often misleading. Hoarseness seldom occurs early in the disease. Frequently the first symptom consists of slight pain or vague discomfort in the throat on swallowing. Persistence of such complaints and progression of their severity are probably the most characteristic subjective features of extrinsic laryngeal cancer. Hoarseness almost always occurs as the second symptom in the moderately advanced stages of the disease, and is due to downward extension of the growth toward the vocal cords or to edema at the level of the cricoid cartilage. The appearance of an enlarged cervical lymph node (discovered by the patient as a "lump in the neck") usually in the region of the carotid bifurcation is third in frequency as the earliest symptom of cancer of the extrinsic larynx. It is significant that such metastatic spread will occur as the initial symptom in about one fifth of the cases. In intrinsic laryngeal cancer metastasis to the cervical lymph nodes almost never occurs as the first symptom.

Viewed through the laryngeal mirror, extrinsic cancer of the larynx usually presents as a fairly bulky lesion (1 to 3 cm. in diameter) when first seen by the physician. The growth characteristically appears as a fungating, papillary tumor of the epiglottis, the aryepiglottic folds, the arytenoids, or the postcricoid region (fig. 10). Occasionally, the lesion presents as a slightly excavated ulcer which has infiltrated deeply. There is almost always accompanying edema that may be sufficient partly to conceal the ulcerated character of the lesion. On the outer or posterior surface of the arytenoids, or in the postcricoid region, slight swelling may obscure the ulcer entirely so that the actual growth can be visualized only by direct laryngoscopy. As cancer of the extrinsic larynx progresses, it tends to invade adjacent structures, and as the edema increases and the growth extends, both dyspnea and dysphagia occur.

Metastasis to the cervical lymph nodes in extrinsic laryngeal cancer frequently takes place fairly early, and almost always in the later stages of the disease. These metastases may become fairly bulky and may compress the cervical nerves to cause intractable pain. Metastasis below the level of the clavicle often occurs if the patient survives the local effects of the disease.

DIAGNOSIS

There is probably no anatomic form of cancer in which avoidable delay in diagnosis may be more readily demonstrated than in malignant tumors of the larynx. There are only three important symptoms in cancer of the larynx, namely, hoarseness in cancer of the vocal cords (intrinsic), and either persistent pain and discomfort on swallowing or the appearance of cervical metastasis in cancer of the extrinsic larynx.

An analysis of large numbers of cases of cancer of the cords reveals that the majority of patients with persistent hoarseness will consult a physician within six weeks. If cancer is suspected and proper investigative steps taken, the true diagnosis will of course be made in all instances. Analysis will also show that when the physician first consulted for hoarseness does not examine the vocal cords but only prescribes medication (gargles, etc.) there is an average delay of over ten months before the true diagnosis is made. Since the patient is assured that his hoarseness is not of serious significance, he tends to procrastinate for weeks or months before further insisting on relief. It is important to emphasize both to the members of the medical profession and to the laity that persistent hoarseness (over two weeks) is almost always serious in character and that it is imperative to find the cause.

In growths of the extrinsic larynx, the early symptoms—minimal dysphagia or the appearance of cervical metastasis—are less impressive than in cancer of the cords, but nevertheless the patient will usually consult his physician within two weeks of the onset. When the patient complains of such symptoms, the physician should realize that the disorder may be serious. An examination of the throat should be made by one experienced in this procedure and in the diagnosis of ailments of the throat. The appearance of an enlarged cervical node, usually termed by the patient "lump or knot in the neck," should always raise the question of metastatic cancer and calls for a thorough search of the mouth and all parts of the pharynx and larynx for the primary source of the tumor.

Differential Diagnosis.—There are numerous lesions occurring in the larynx which may simulate cancer clinically. These are: benign mucous polyps, pachyderma, papilloma, tuberculosis and syphilis. Elaborate descriptions have been published in the past to aid in the clinical differentiation between such diseases and laryngeal cancer. Even to the thoroughly experienced, a differential diagnosis based on clinical characteristics alone is often inaccurate. Only by microscopic examination of a biopsy specimen can a diagnosis be definitely made.

A biopsy specimen can be removed from most parts of the extrinsic portion of the larynx by a curved biopsy forceps guided by a laryngeal mirror. Biopsy of lesions in the intrinsic part of the larynx and the postcricoid region usually requires direct laryngoscopy.

TREATMENT

During the past fifteen years there has been a great deal of partisan and often prejudiced discussion as regards the most effective method of treatment for cancer of the larynx. Such controversy is to be expected, for the power of speech is considered to be one of the most precious of human attributes and one which distinguishes man from the lower animal. When cancer affects the larynx and a method of treatment is proposed to the patient which would deprive him of this function, the natural reaction of both the patient and his physician is one of reluctance and resistance, and any alternative method which promises to cure cancer of the larynx with preservation of this organ and of the function of speech deserves serious consideration.

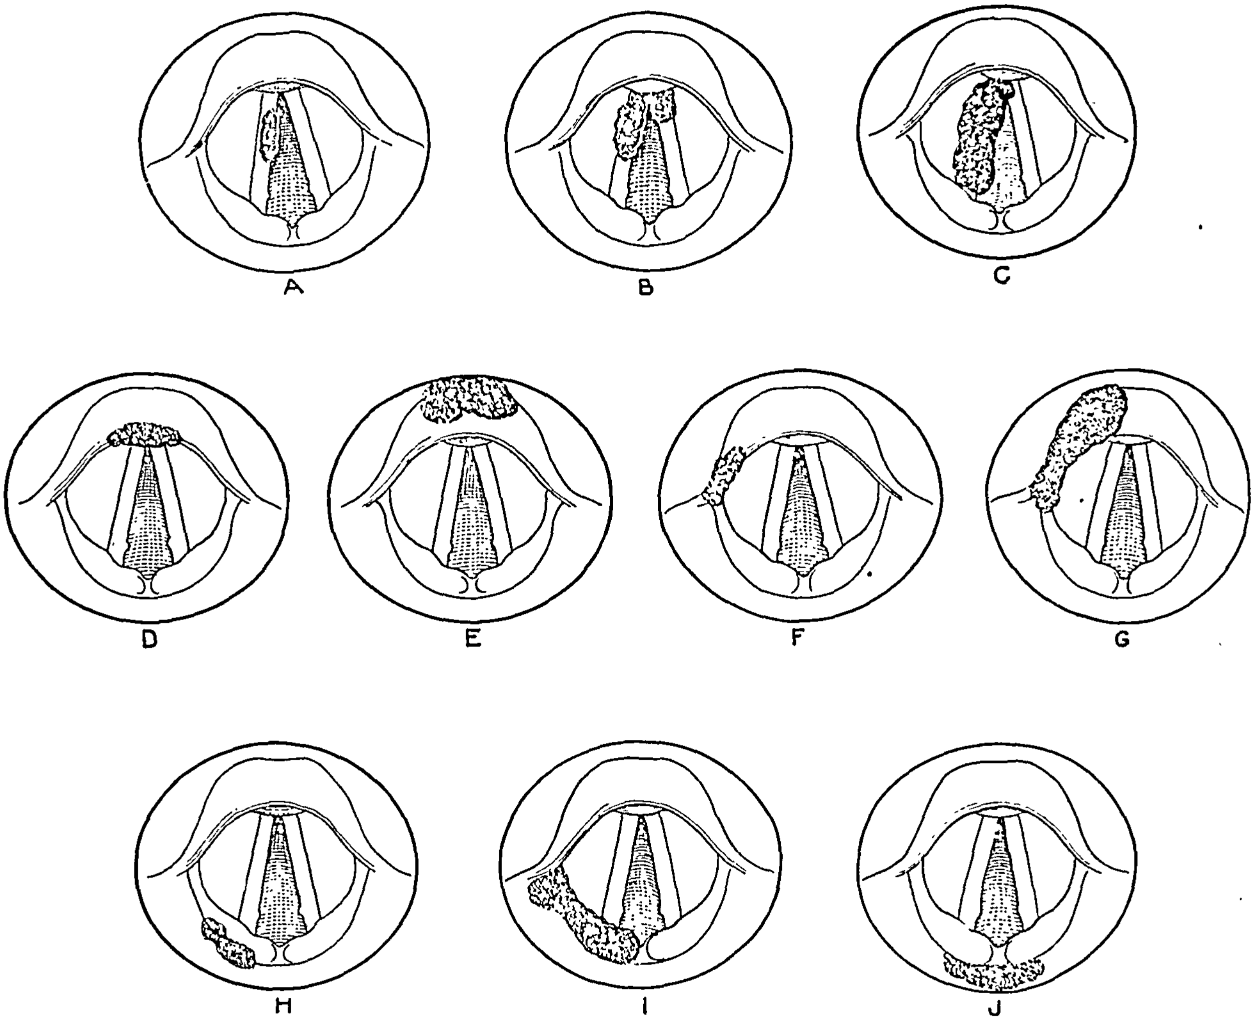

Fig. 10.—Cancer of the larynx as seen through the layrngeal mirror. The lesions as shown are reasonably early. In the more advanced stages, the appearance is variable and often somewhat confusing as to the exact point of origin. Top row: Cancer of the Intrinsic Larynx. (*a*) Lesion limited to about one third of one vocal cord. (*b*) Spread of the growth into the anterior commissure to involve the opposite cord. (*c*) Further progress of cordal cancer. Middle and bottom rows: Cancer of the Extrinsic Larynx, showing the most common variations in point of origin. (*d*) Base of epiglottis. (*c*) Tip of epiglottis. (*f*) Lateral aspect of epiglottis. (*g*) Epiglottis and aryepiglottic fold. (*h*) Lateral aspect of arytenoid. (*i*) Aryepiglottic fold and arytenoid. (*j*) Postcricoid region.

Fractionated radiation therapy for cancer of the larynx brought about some promising initial results, and formerly it was hoped and firmly believed by many that with further experience and refinements in technic the method would completely supplant surgery in the treatment of this disease. Such early hopes have not been sustained by the experience of the past twenty years. Radiation therapy will cure a small percentage of cases of laryngeal cancer, both extrinsic and intrinsic. This method of treatment, however, is uncertain and fraught with serious complications that may arise at any time, even years following completion of therapy, because of the degenerative effects of radiation on normal tissues in this area, even though the cancer itself is cured.

At the present time, it can be stated without question that surgical treatment (partial or total laryngectomy) will cure a higher percentage of cases of both extrinsic and intrinsic laryngeal cancer than will radiation therapy provided that the growth is in an operable stage. Surgery is, therefore, the method of choice from the standpoint of chance of cure and of saving life. Unfortunately, in cancer of the extrinsic part of the larynx (epiglottis, aryepiglottic folds, arytenoids, postcricoid region and ventricular bands) only about 1 in 3 cases has so far been considered operable, so that for the remaining two thirds of the cases radiation therapy has been the only alternative. The latter method will result in a small but definite number of cures in these otherwise inoperable and incurable patients.

Briefly stated, the indications for treatment in cancer of the larynx from the standpoint of obtaining the highest percentage of cures in all comers is as follows: early cancer of the intrinsic larynx—partial laryngectomy through laryngofissure; moderately advanced cancer of the intrinsic larynx—total laryngectomy; advanced cancer of the intrinsic larynx—total laryngectomy; early and moderately advanced cancer of the extrinsic larynx—total laryngectomy; advanced and inoperable cancer of the extrinsic larynx—radiation therapy.

After consideration of the aforementioned groups there still remains a small number of cases which do not fit into any of these classifications of treatment, such as locally recurrent cancer after total laryngectomy and cervical metastasis in both operable and inoperable cases. Many of these patients are still suitable subjects for further surgical treatment, but in the majority of such cases roentgen and radium therapy combined with surgical treatment is the best solution of the problem.

Cervical metastasis is not a frequent problem in cancer of the intrinsic larynx, for such spread usually occurs at an interval of several months or even years following surgical removal of the primary growth. In these cases, neck dissection is the method of choice of treatment (unilateral or bilateral). When metastasis occurs in cases of inoperable cancer of the extrinsic larynx, a program of radiation therapy may be employed and the treatment should be directed toward the metastatic nodes as well as the primary lesion. In other situations, operable metastases are present on admission in cases of operable primary lesions in the extrinsic or intrinsic part of the larynx. In these, it is often possible to remove the larynx and make a neck dissection in either one or two stages.

PROGNOSIS AND END RESULTS

The five year cure rate in cancer of the larynx as obtained in one clinic is given in table 2. This group includes all patients applying to a single institution—early, far advanced, primary or recurrent cancer following surgical treatment or radiation therapy elsewhere.

The prognosis in laryngeal cancer is influenced by a number of factors, the most significant of which are the size of the growth and the presence or absence of metastasis to cervical lymph nodes. The importance of these factors can be plainly demonstrated by the fact that when the tumor on the vocal cord measures 1 cm. or less in diameter a five year cure of 95 per cent may be obtained by partial laryngectomy through laryngofissure. The rate of cure in larger lesions of the intrinsic part of the larynx and in any lesion of the extrinsic part of the larynx is definitely lower.

IV. CANCER OF THE NECK

In a discussion of malignant tumors of the neck it is essential first to emphasize that the most frequent variety of cancer in this area is metastasis to the cervical lymph nodes from primary sites outside the neck and that only a small proportion of cancer in this region arises primarily in the structures of the neck. This difference is not always appreciated, so that erroneous diagnoses are made in ascribing a local origin to a cervical tumor and disregarding the probability that a primary lesion of cancer may be present in the mouth, pharynx, skin of the face or scalp or even in some viscus below the clavicle.

Although most malignant neoplastic disease in the neck is metastatic, there are several varieties of tumors which arise primarily in the cervical structures, namely, malignant lymphoma, thyroid cancer, tumors of parotid or submaxillary salivary glands and sarcoma of the soft parts (muscle, fascia, nerve). Among the less frequent primary growths arising in the neck are branchioma, tumor of the carotid body and cervical chordoma. These morphologic varieties will be discussed under separate headings.

METASTATIC CERVICAL CANCER

Asymmetric enlargement of the cervical lymph nodes in the adult is almost always malignant and usually due to metastasis from a primary lesion in the mouth or pharynx, and occasionally from a viscus below the level of the clavicle. Cervical metastatic cancer occurs more frequently than any other form of malignant neoplastic disease in this locality, so that no other diagnosis should be made except by exclusion of such a probability. When asymmetric enlargement of cervical lymph nodes is encountered in children, it may be due to metastasis, although this possibility is less likely than in adults.

The details of the lymphatics of the neck have been thoroughly investigated by anatomists. In certain sites nodes occur so consistently that they have been given definitive anatomic designations, such as the internal jugular chain, the subdigastric node, the spinal accessory chain, the prevascular and retrovascular submaxillary nodes and the preglandular node (fig. 11). Enlargements of cervical nodes in these specific areas, especially if asymmetric, always suggest the probability of metastatic cancer. It must be realized, however, that the diagnosis and treatment of such metastasis alone is entirely inadequate unless the primary lesion is also discovered and treated at the same time.

Diagnosis of Cervical Metastatic Cancer.—For practical purposes a lymph node cannot be considered abnormal unless it is enlarged, but a distinction must be made between enlargement and palpability. Lymph nodes are palpable in the majority of normal subjects. Asymmetry is the only truly significant clinical characteristic of enlargement of a lymph node.

One of the greatest errors in the diagnosis of cervical tumors or enlargement of lymph nodes is the immediate excision of a tissue specimen for biopsy, for even though the presence of malignant neoplastic disease in the neck is thereby proved, the diagnosis is incomplete, nevertheless, until the primary lesion is found. The local excision of a node in the neck as the primary procedure for cancerous lesions greatly decreases the prognosis for cure. If the physician eventually will have to refer a patient with a biopsy diagnosis of metastatic cervical cancer elsewhere for treatment, then logically he should make this disposition before rather than after the biopsy. If, on the other hand, he is willing to assume the entire responsibility for the management of the case, then he is obliged to make a thorough search for a primary lesion in the mouth or pharynx first, using incisional biopsy of the lymph node only as the last resort.

Aspiration Biopsy.—A useful diagnostic measure in tumors of the neck is aspiration biopsy. With this procedure the clinical picture is in no way altered and a positive microscopic diagnosis may be obtained in most cases. A histologic diagnosis established by aspiration biopsy will indicate tentatively whether the growth is primary or metastatic, will often yield clues as to the possible location of the primary lesion and occasionally disclose the presence of benign cysts and chronic inflammatory disease (tuberculosis, Boeck's sarcoid, etc.)

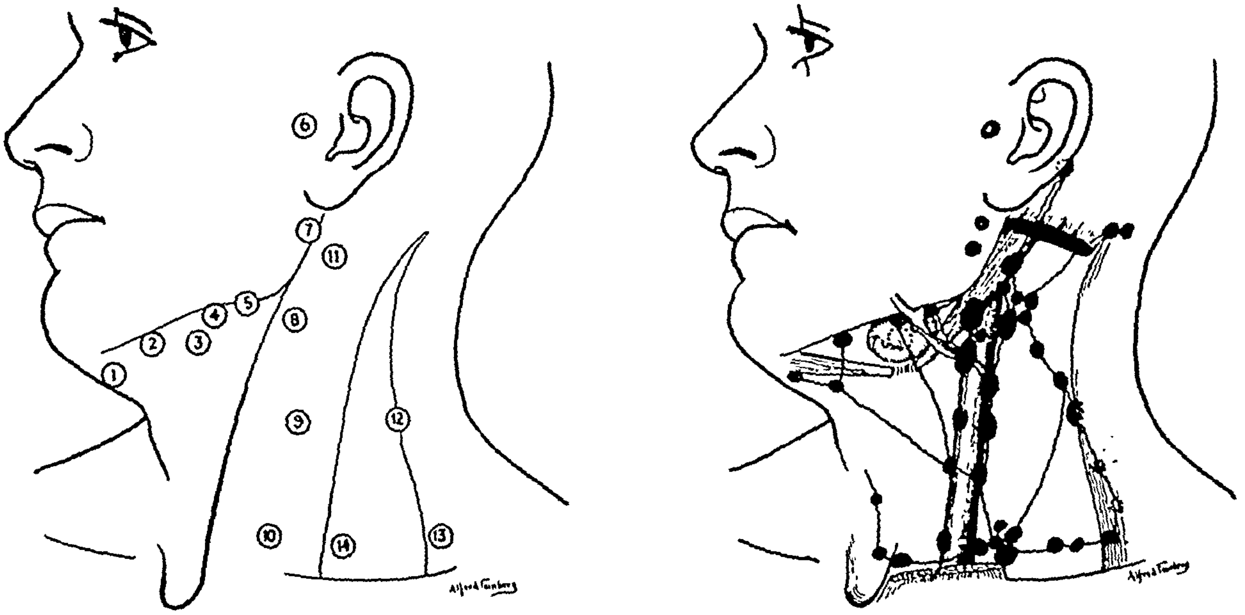

Fig. 11.—Deep lymphatics of the neck. Although the anatomy of the cervical lymphatics is somewhat variable there are, nevertheless, certain constant features; that is, lymph nodes are always present in certain areas and therefore these nodes or node groups can be assigned specific names. Index of main nodes and groups of nodes: (1) submental group: (2) preglandular, (3) intraglandular, (4) prevascular and (5) retrovascular; submaxillary group: (6) preauricular and (7) infra-auricular; parotid group; (8) subdigastric, (9) midcervical and (10) lower cervical; internal jugular chain; (11) upper, (12) middle and (13) lower spinal accessory chain; (14) transverse cervical chain.

Treatment of Cervical Metastatic Cancer.—The treatment is inescapably a part of the problem of management of the primary lesion and for that reason will not be discussed here.

MALIGNANT LYMPHOMA (LYMPHOSARCOMA AND HODGKIN'S DISEASE)

Malignant lymphoma of the cervical nodes may be divided into two general varieties—lymphosarcoma and Hodgkin's disease. The former occurs with considerably greater frequency in the head and neck than does Hodgkin's disease.

Lymphosarcoma is encountered in all age groups but is most commonly seen in the fifth and sixth decades of life. Males are affected as often as females. The most usual site for a primary lesion of lymphosarcoma in the upper respiratory and alimentary tracts is in the tonsil (50 per cent of cases).

Both lymphosarcoma and Hodgkin's disease may originate in the cervical lymphatics, or involvement of these nodes may be part of a generalized process. Lymphosarcoma may arise in any of the lymphoid structures of Waldeyer's ring (nasopharynx, base of tongue, tonsil) and is occasionally metastatic to the cervical nodes, taking the same route as epidermoid carcinoma. It is impossible to distinguish malignant lymphoma of the neck from metastatic cervical carcinoma by clinical examination alone, although lymphomatous tumors in general tend to be more rapid in growth, softer and bulkier than tumor metastasis of epithelial origin. The number of nodes involved by lymphosarcoma tend to be less than in Hodgkin's disease, and in the latter there is usually more induration. None of these clinical characteristics is constant enough to be of significant diagnostic value.

Diagnosis of Malignant Lymphoma.—The diagnosis of malignant lymphoma of the neck can be made only by the exclusion of other forms of cervical cancer and is based on a histologic study of tissue removed from the tumor. In some cases it may be possible to make a diagnosis on aspiration biopsy alone, but usually the pathologist, although suspecting malignant lymphoma, will request an incisional biopsy for this particular group of neoplastic diseases.

Treatment of Malignant Lymphoma.—Lymphosarcoma is one of the more radiosensitive of malignant tumors, and in most cases the initial response to radiation therapy will be good. Further, the uncertainty of the course of the disease makes surgical treatment undesirable, so that with the diagnosis of lymphosarcoma radiation therapy is the accepted treatment.

In the past it has been recommended by some that the dosage should be small or at least not more than moderate, both because the disease is radiosensitive and because of the widespread belief that lympsosarcoma is a constitutional disease from the beginning (heterotopic origin). Long range clinical observations and investigation in the treatment of lymphosarcoma of the head and neck do not support this concept. The cure rate of lymphosarcoma of the head and neck, whether primary in the cervical lymph nodes or metastatic from the tonsil or pharynx, gives even a better prognosis when treated with radiation therapy than epidermoid carcinoma (52 per cent five year cure rate), but the dosage must be maximal rather than minimal (the same as for epidermoid cancer).

When Hodgkin's disease involves the cervical nodes, there is usually clinical or roentgenographic evidence of disease elsewhere in the body, particularly in the thorax or abdomen. Since the lesions of this variety of malignant lymphoma are radiosensitive and frequently widespread on admission, these patients are best treated with radiation therapy, after the diagnosis has been confirmed histologically by aspiration or incisional biopsy. In an occasional case in which the disease in the neck is not too extensive or bulky (preferably unilateral) and careful physical and roentgenographic examination reveals no evidence of involvement elsewhere, treatment by neck dissection may be employed.

CANCER OF THE THYROID GLAND

Malignant tumors of the thyroid gland, though relatively uncommon, are among the most interesting in the field of oncology because of the wide variation and unpredictability of their behavior and their clinical resemblance to several more common benign forms of thyroid tumors and enlargements.

Cancer of the thyroid comprises about 0.4 per cent of all human cancer. Females are affected more often (65 per cent) than males. The median age is 52 years. Although the growth occurs most often in the 40 to 60 year age groups, thyroid cancer is more frequently encountered in children than most other varieties of malignant tumors in the head and neck.

Causative Factors in Thyroid Cancer.—Nothing is known as to the direct cause of thyroid cancer. Carcinoma is occasionally seen to originate in nodular (adenomatous) goiter and in fetal adenoma. Although a specific causal relationship between these lesions and thyroid cancer has not been conclusively demonstrated histologically, nevertheless, the occurrence of cancer in about 5 per cent of such thyroid lesions indicates that they play a significant role in its etiology.

Pathology of Thyroid Cancer.—In most cases the growth consists of low grade papillary adenocarcinoma, usually metastasizing to the cervical lymph nodes relatively late in the course of the disease. Other morphologic varieties of cancer which occur though rarely in the thyroid gland are spindle and giant cell, Hürthle cell and anaplastic carcinoma.

Symptoms and Clinical Course of Thyroid Cancer.—The symptoms of cancer of the thyroid gland are seldom pronounced in the beginning. The patient usually finds a "lump in the neck" and seeks medical advice after varying intervals with no other complaints. In a smaller proportion of cases the patient discovers "lumps in one or both sides of the neck," which are usually metastases from the primary growth in the thyroid, and seeks medical advice for this reason. In the latter instance, the alert physician may note a mass in the thyroid gland of which the patient was not aware, or physical examination may fail to disclose any thyroid tumor. Nevertheless, such a primary lesion will invariably be established at operation.[1]

The history of the cervical tumor, whether in the lymph nodes or in the thyroid itself, is fairly long (several months to three to five years). The clinical course of this disease is so slow that sometimes metastatic masses in the neck will have reached the size of 8 to 10 cm. in diameter before a physician is consulted, by which time such metastases may overlie one lobe of the thyroid, completely obscuring the presence of a primary thyroid neoplasm.

In other cases, the tumor apparently remains confined to the thyroid itself, and over a period of years undergoes steady growth to reach a size of 10 cm. or more in diameter; the mass, which is confined by the overlying strap muscles, produces gradual pressure, displacing the esophagus and trachea so that the first symptoms are progressive dyspnea and dysphagia. At this stage of the disease, the growth may or may not have actually invaded the trachea, esophagus or recurrent laryngeal nerve, or cervical lymph node or systemic metastases may have occurred. Occasionally, the tumor, confined beneath the strap muscles, will encounter less resistance to downward extension into the superior mediastinum. A malignant neoplasm of the thyroid which arises on the posterior aspect of one lobe may press on or invade the recurrent laryngeal nerve fairly early in the course of the disease, with hoarseness as the first serious symptom.

If thyroid cancer is uncontrolled, the most frequent cause of death is from the local effects of the disease, namely pressure on and invasion of the trachea and esophagus. As the disease in the neck or mediastinum advances, death will occur from respiratory obstruction, which is not readily relieved by tracheostomy since the trachea is markedly distorted or often directly invaded by the growth below the level of the manubrium. If the local tumor has been completely or partly removed and the serious effects of tracheal obstruction prevented or relieved, metastasis to bone, lungs or other viscera may take place at any time up to twenty years. In any case, the progress of the disease tends to be slow.

Diagnosis of Thyroid Cancer.—A tumor in the lower anterior portion of the neck which moves upward with the larynx and trachea on swallowing is almost always of thyroid origin. There are no distinguishing clinical characteristics, however, between early cancer of the thyroid and benign adenoma containing cancer.

A diagnosis of a malignant tumor in this gland is often made on routine histologic examination of the surgical specimen following the frequently performed procedure of partial thyroidectomy for nodular goiter (benign adenoma). When a mass in the thyroid resembling adenoma is found to be unusually hard and irregular in contour, rather than smooth or nodular, a tentative diagnosis of cancer should be made and steps taken to establish a histologic diagnosis by aspiration biopsy before deciding on the method of treatment, or at least a frozen section should be obtained at the time of operation.

---

[1] It has not been definitely settled whether aberrant thyroid tissue in the neck can give rise to aberrant thyroid cancer or whether such masses outside the thyroid are actually metastatic from small primary growths in the thyroid. There is evidence to indicate that such an entity as aberrant thyroid cancer does exist, but the diagnosis is too frequently and loosely made. In most cases first considered as cancer of aberrant thyroid origin, a growth of similar histologic character can be found in the corresponding lobe of the thyroid if a careful search is made at operation, and in some of these the primary lesion in the thyroid can only be demonstrated microscopically.

The possibility of a malignant growth in the thyroid should be kept in mind in all cases of enlargement of cervical lymph nodes. In the search for a primary lesion; both before and after a histologic diagnosis of metastatic cancer in the cervical nodes has been established, a thorough search of the oral cavity and pharynx should be followed by palpation of the thyroid. Even the smallest nodular enlargement in any portion of the gland should be considered significant. An aspiration biopsy of a mass in the neck may suggest to the pathologist the most likely site of the primary lesion (thyroid, lung, pharynx, etc.).

In all instances of unilateral paralysis of the larynx (recurrent nerve) particular attention should be paid to the possibility of a thyroid neoplasm, palpating deeply in the region between the trachea and the spine. In some of these cases evidence of a substernal growth may be disclosed on roentgenographic examination of the chest which must be differentiated from other causes of recurrent nerve paralysis such as mediastinal tumors of nonthyroid origin or aneurysm of the aorta.

Treatment of Thyroid Cancer.—One of the basic principles underlying the treatment of thyroid cancer is the recognition that the growth may arise in or clinically resemble benign adenoma. That is the reason why all thyroid tumors should be excised, preferably by complete removal of the affected lobe or lobes. Furhermore, all excised thyroid adenomas should be subjected to histologic examination for the presence of unsuspected malignant neoplastic disease. If a small cancer is discovered in an excised adenoma after routine histologic examination of the surgical specimen and there is no clinical evidence of cervical metastasis, nothing further should be done except systematic follow-up examination of the patient.

When a definite diagnosis of thyroid cancer can be established preoperatively (aspiration biopsy), the treatment of choice is a wide resection of that portion of the gland containing the tumor (hemithyroidectomy) combined with a homolateral block dissection of the neck (removal of the internal jugular vein, sternomastoid and strap muscles, submaxillary salivary gland and accompanying lymph nodes). The removal of the internal jugular vein is a significant part of the surgical treatment of thyroid cancer, since metastasis so commonly invades veins.

As already mentioned, the average malignant tumor of the thyroid is not radiosensitive and if the growth is operable, radiation therapy should never be used as the primary method of treatment. In most cases neither preoperative nor postoperative radiation therapy is indicated. Cancer-lethal doses of radiation given to the thyroid will frequently produce edema of the larynx and increase the hazard of obstruction to the airway without appreciably affecting the local disease.

Due to the relatively benign course of early cancer of the thyroid many patients will be seen for the first time in the later stages of the disease. In these cases, there may be widespread visceral or skeletal metastasis. Nevertheless, the primary tumor in the thyroid should be excised as widely as possible for palliative reasons. If this can be done and the complications due to pressure on the trachea and esophagus relieved, the patient may live for a period of several years before succumbing to the effects of generalized metastasis.

In clearly inoperable cases a judicious amount of radiation therapy may be used if there is histologic or other evidence (absorption of radioactive iodine) of radiosensitivity. In all forms of painful osseous metastasis, radiation therapy may offer some measure of relief. Within recent years, it has been hoped that radioactive iodine might prove of value in the treatment and possibly the cure of thyroid cancer. Unfortunately, only about 15 per cent of malignant thyroid tumors will pick up this isotope, and only in this group can any favorable effect be expected. In an occasional case, the administration of radioactive iodine has brought about considerable amelioration of symptoms and regression of local recurrences, and it is hoped that in these some cures may eventually be obtained.

Prognosis and End Results of Thyroid Cancer.—As previously mentioned, the immediate prognosis in thyroid cancer is almost always good. In all comers, the cure rate is about 25 per cent, but if the disease can be discovered and adequately treated in the early stages it carries one of the best prognoses of any form of cancer.

SARCOMA OF THE SOFT PARTS OF THE NECK

Malignant tumors of the soft parts of the neck exhibit the same clinical and anatomic characteristics as soft part neoplasms in other parts of the body. Sarcoma may arise in almost any tissue—muscle (myosarcoma), nerve (neurogenic sarcoma), connective tissue (fibrosarcoma), fat (liposarcoma), blood vessels (angiosarcoma), etc. When the histogenesis cannot be established such growths are usually referred to by the over-all term "spindle-cell sarcoma."

Malignant tumors of the soft somatic tissues occur more often on the extremities and are encountered less frequently in the neck. This morphologic variety of cancer when it occurs in the neck is found in larger proportions among the younger age groups and in children.

Little can be said about their clinical characteristics. They may originate in any part of the neck (anterior, lateral, posterior) and grow outward to form bulky masses or inward to compress the trachea or esophagus. They are more infiltrating in nature than malignant tumors of epithelial origin and in most cases are radioresistant. Radical surgical removal offers the best chance of cure, although, as with sarcoma in general, pulmonary metastasis is a frequent occurrence.

BRANCHIOGENIC CANCER

Malignant branchioma (branchiogenic cancer) refers to those malignant tumors which are believed to arise in the vestigial remnants of the embryonal branchial apparatus. Such a diagnosis is too often made in the case of neoplasms appearing in the lateral aspects of the neck and presumably unassociated with a primary growth elsewhere.

Experience in cancer clinics has shown that the overwhelming majority of malignant tumors which arise in the neck are metastastic from a silent primary neoplasm somewhere in the mouth or pharynx, or even from a site below the level of the clavicle. Less often, such primary cervical neoplasms originate from one of the major salivary glands or other tissues in the neck (muscle, connective tissue, nerve, etc.). The diagnosis of malignant branchioma can rarely be justifiably made, since the primary lesion of cancer in the mouth or pharynx may remain silent or of such small size as to be undemonstrable for a period of several years. This diagnosis is not reasonable, therefore, except after an observation period of five years following treatment of the cervical tumor. Up to that time the diagnosis of malignant branchioma must remain tentative only.

Morbid Anatomy and Clinical Characteristics of Malignant Branchioma.—The vestigial remnants of the branchial apparatus are situated on a line extending just anterior to the tragus of the ear, downward along the medial border of the sternomastoid muscle to the clavicle. Anatomically, therefore, branchial cancer cannot occur in any other region of the neck. Histologically, the tumor should logically be epithelial cancer (epidermoid carcinoma, adenocarcinoma), but since the embryonal branchial apparatus also contains other tissue components (muscle, connective tissue, nerve, etc.), it is theoretically possible for branchial cancer to occur in the form of myosarcoma, fibrosarcoma, etc. In the cases finally diagnosed as malignant branchioma no clinical features have been found which differ from those of metastatic cancer or of primary soft part tumors occurring along this line.

In general, it might be said that the diagnosis of malignant branchioma is too often and too loosely made. There may even be some doubt as to whether there is justification for such a morphologic entity, since no definite evidence has ever been produced to show that such a specific tumor actually exists. Adequate proof could only be the demonstration of cancer arising in the walls of a branchial cyst. This, so far as can be learned, has never been demonstrated.

CANCER OF THE CAROTID BODY

There are several tiny seedlike structures belonging to the chromaffin system which are situated in the region of the bifurcation of the carotid artery and designated as the carotid bodies. Tumors arising in these structures are among the rarest in the realm of neoplastic disease. In one cancer clinic where about 2,000 patients with neoplasms in the head and neck are seen yearly only 15 cases were encountered during the past ten years.

These tumors usually arise after puberty, pursue a chronic, relatively benign course and do not produce remote metastasis. Although a tumor of the carotid body usually grows slowly, remaining about 3 cm. in diameter over a period of ten to fifteen years, it may on occasion grow more rapidly and reach a size of 8 to 10 cm. or even larger. This neoplasm produces little discomfort except in rare instances in which pain is a prominent factor.

A tumor of the carotid body is located either on or behind the bifurcation of the common carotid artery, which is often compressed or invaded by the growth. It may grow upward toward the skull, inward toward the tonsillar region and pharynx or outward, producing a bulge in the neck.

A diagnosis of this specific neoplasm can be made only on histologic examination of a biopsy specimen. It may be suspected, however, when a growth occurs just below the angle of the mandible and over which there can be felt a prominent arterial pulsation, indicating that the tumor lies at least partly beneath the great vessels at this point. Aspiration biopsy will in most instances establish a definite diagnosis.

In most cases of carotid body tumor the underlying principle of treatment should be that of *noli me tangere*, for so far as is known the clinical course of the growth is almost always benign (nonmetastasizing). In general, surgical removal should be considered hazardous, for it is not possible to determine beforehand whether the neoplasm is so closely attached to the carotid crotch that it can be removed without sacrificing the integrity of the vessel wall. When such an injury occurs, it is usually impossible to repair the artery and the common or internal carotids must be ligated. It is well known that ligation at these points is attended by an operative mortality rate of about 50 per cent. If a diagnosis of tumor of a carotid body, therefore, can be established by aspiration biopsy and if the growth is not causing any symptoms, no treatment whatever should be administered. If the tumor is producing symptoms (pain) and removal is attempted, it is more prudent to leave a portion of it attached to the great vessels than to subject the patient to any undue risk. No regression of this neoplasm can be obtained with radiation therapy.

CHORDOMA

Chordoma is a rare tumor. In the head and neck it may present at the base of the skull, in the nasopharynx, retropharyngeal and parotid areas or in the lateral and posterior aspects of the neck. There is usually a history of fairly long duration when the patient is first seen, and if the growth presents in the neck a diagnosis of parotid tumor may be erroneously made.

Although the clinical course of chordoma is usually slow, the neoplasm may become widely invasive and by pressure erode the bones of the spine or base of the skull. If a preoperative diagnosis of chordoma can be established histologically (aspiration biopsy), treatment should be planned on the basis of relief of current symptoms only. Due to its origin from embryonal notochord tissue, it is impossible to effect a complete removal surgically. Nevertheless, if the projecting portions of the tumor which are causing symptoms (especially pressure on nerves) are removed, healing will take place and the patient can be afforded considerable relief. Chordoma is generally a radioresistant growth.

V. CANCER OF THE MAJOR SALIVARY GLANDS

The major salivary glands consist of the paired parotid, submaxillary and sublingual glands. Tumors occur most frequently in the parotid (about 85 per cent), less often in the submaxillary (about 15 per cent) and rarely in the sublingual gland.

When a series of tumors of the salivary glands are reviewed from the pathologic standpoint their appearance will be found to vary from a relatively acellular structure of cartilage and mucin through the more cellular types, up to a picture of highly malignant carcinoma. The transition from one extreme to the other is a gradual one, so that in the middle range there will be found a considerable number of cases in which the opinions of individual pathologists will vary as to whether given tumors should be classified as malignant or benign. Although the same can be said of many forms of cancer, this morphologic problem is of particular significance in tumors of the major salivary glands.

All benign mixed tumors of the salivary glands have a tendency toward malignant degeneration. It has been repeatedly demonstrated that in mixed tumors of the parotid which have recurred after repeated surgical removal over a period of fifteen to twenty years and in which the original surgical specimen showed only a benign histologic pattern, a high incidence of malignant transformation finally occurred, resulting in the patient's death. Occasionally an initial surgical specimen of what appeared clinically to be a benign mixed tumor is found to show malignant changes.

In the majority of cancers of the salivary glands the malignant character of the growth is clinically apparent when the patient is first seen and it is plain that the tumor was cancer from the beginning, rather than originating in a benign tumor. In the parotid gland about 25 per cent of all tumors are malignant, and in the submaxillary gland the proportions are somewhat reversed (about 25 per cent benign). Neoplasms, either benign or malignant, rarely occur in the sublingual salivary gland.

MORBID ANATOMY AND CLINICAL COURSE

In tumors of th major salivary glands the symptom first noted by the patient is almost invariably a "lump" in the parotid or submaxillary region. In the average case, the patient has been aware of this abnormality for many months or even years before medical advice is sought. The clinical course is characteristically slow. When first seen by the examining physician, the growth may have advanced in size from a few millimeters to 8 or 10 cm. and is usually movable. The smaller tumors are smooth in contour, but in those over 5 cm. in diameter nodularity is a common feature. The growth is invariably unilateral and single; multiple tumors occur only as recurrences after incomplete surgical excision (seeding).

Most tumors of the salivary glands, even when malignant, tend to be noninvasive, so that as enlargement occurs they displace rather than infiltrate the adjacent structures. As a result, the branches of the facial nerve will usually be pushed aside as the growth advances in the parotid gland, and facial paralysis is rarely present in the early or uncomplicated cases. When the seventh cranial nerve is compressed or actually infiltrated by a malignant tumor of the parotid with resulting facial paralysis, the growth in most cases is relatively far advanced or recurrent. As the tumor grows it tends to migrate toward the outer surface of the parotid gland (the direction of least resistance). When the growth arises in the deep (retromandibular) portion of the gland, lateral extension is at least partially blocked by the ascending ramus of the mandible, and therefore it tends to advance mesially toward the pharynx and may even present as a bulge in the tonsillar area.

In general, cancer of the parotid tends to remain fairly well localized, eventually producing death mainly by local extension of the disease to the structures of the middle ear and mastoid, pharynx, neck and base of the skull with sepsis, malnutrition, pain and hemorrhage. Except in cases in which the primary growth in the parotid is controlled, metastases do not often play a large part in the cause of death. If the patient survives the local effects of the disease long enough after the disease is controlled, local metastasis occasionally occurs first to the cervical lymph nodes and then systemically.

Tumors of the submaxillary salivary gland resemble parotid growths in their symptoms and clinical course with few exceptions; that is, the patient complains of a slowly enlarging lump of several weeks' or months' duration in the submaxillary area. To palpation these tumors tend to be firm, discrete and often nodular. It has already been mentioned that there is a higher percentage of malignant tumors in the submaxillary gland as compared with the parotid. Although there are no symptoms referable to the seventh cranial nerve in cases of submaxillary tumors, this gland is closely associated with the lingual branch of the trigeminal nerve (sensory), so that pain is often a prominent early symptom, especially in the invasive malignant growths.

DIAGNOSIS

There are several neoplastic and chronic inflammatory lesions in or about the parotid and submaxillary glands which clinically may simulate a benign or primary malignant tumor in these structures and which must be considered in the differential diagnosis. These are chronic parotitis, inflammatory hypertrophy of the preauricular lymph nodes, lymphoma, Boeck's sarcoid, cervical neurofibroma or schwannoma, branchiogenic cyst, Warthin's tumor (papillary cystadenoma lymphomatosum) and metastatic cervical cancer (from the scalp or eye, especially melanoma). A calculus in the submaxillary salivary gland or Wharton's duct is frequently associated with chronic sialitis and clinically may resemble a growth in this structure in every way. A diagnosis of calculosis may be established by roentgenographic studies.

Although there are numerous features in the history and physical examination which help in the differential diagnosis of tumors of the major salivary glands a definite diagnosis can only be made by biopsy. Aspiration biopsy is of distinct value in establishing a histologic diagnosis of a neoplasm in the parotid or submaxillary gland, for if an incisional biopsy with subsequent postoperative scarring can possibly be avoided, exposure and excision of a tumor in the parotid or submaxillary regions can be technically more easily accomplished.

The occurrence of tumors in the sublingual salivary gland is rare, and the diagnosis invariably difficult. It must be distinguished from cancer of the floor of the mouth. Growths in the latter region, whether benign or malignant, will be found to extend into the floor of the mouth anteriorly. It may sometimes be difficult to differentiate clinically between sublingual and submaxillary tumors. If the mass is situated in the floor of the mouth but apparently not arising from mucous membrane, a tentative diagnosis of tumor of the sublingual salivary gland may be made.

TREATMENT

In general, tumors of the salivary glands are not radiosensitive and the only effective method of treatment is surgical. As already mentioned, the clinical course of these neoplasms is always progressive with a tendency toward malignant degeneration. In the parotid, paralysis of the facial nerve will eventually occur in most cases whether or not the tumor is malignant. For these reasons all tumors of the salivary glands should be excised and the earlier the neoplasm is removed the better the prognosis. The argument that parotid tumors should be allowed to "ripen" before they are excised is fallacious. If such a policy of procrastination is followed, nothing is accomplished except to permit the growth to progress and possibly undergo malignant changes

In considering the operative approach for parotid tumors, the surgeon should realize that these growths are often deceptive in that on clinical examination they appear to be more superficial and accessible than actually proves to be the case on operation. For this reason, many patients with parotid tumors are operated on in doctors' offices or in hospitals with incomplete preparation and limited surgical exposure, only to find a deep-seated growth of unanticipated proportions and extent which cannot be completely removed with such inadequate facilities.

The surgical exposure for excision of a parotid tumor should be liberal—usually in the form of a Y incision, two arms of which run up in front of and in back of the lobule of the ear and a third arm of which is extended downward and forward into the upper part of the neck. The surgeon should decide in the beginning whether in the given case adequate hemostasis requires preliminary ligation of the external carotid artery, which can be accomplished through the lower arm of the incision. One of the most important precautions in the removal of a parotid tumor is avoidance of injury to the seventh cranial nerve. The best way to prevent such an accident is first actually to expose the main trunk of the nerve where it emerges from the stylomastoid foramen and then to proceed to dissect out the growth. Exposure of the major branches of the facial nerve is essential for an adequately wide removal of a deeply seated tumor. Obviously, if the nerve or one of its major branches has been invaded by cancer, it must necessarily be sacrificed for the more important purpose of saving life. In general, it can be stated that a surgeon should not attempt the removal of a parotid tumor unless he has previously dissected out this gland in a cadaver with preservation of the facial nerve and its plexus. The undergraduate instruction on the anatomy of the facial nerve given in medical schools is inadequate preparation for one who is to cope with this operation.

The question of neck dissection at the time of removal of the parotid tumor must be determined on the basis of the morbid anatomy and histologic character of the growth.

The tumor of the submaxillary salivary gland offers no difficulty from the surgical standpoint. Its removal requires only complete dissection of the submaxillary triangle; this area contains no important structures except the hypoglossal nerve and the lingual branch of the fifth cranial nerve, which are readily accessible and easily preserved. If invaded by the growth, either one of these structures can be sacrificed. In the excision of a submaxillary tumor it is important to determine beforehand whether the lesion is benign or malignant. If the neoplasm is malignant (adenocarcinoma, adenoid cystic carcinoma, etc.), a block dissection of the neck should be done at the same time.

PROGNOSIS AND END RESULTS

So far as benign mixed tumors are concerned, the growth itself rarely results fatally. With proper treatment (complete surgical excision) a cure rate of 100 per cent should be obtained in previously untreated benign tumors, and almost 100 per cent even in previously treated patients, that is, in those with incomplete excision or pronounced scarring and fibrosis due to radiation therapy.

Nevertheless, these benign growths do constitute an eventual hazard to life, since they may undergo malignant transformation. While many tumors of the major salivary glands are malignant from their inception, others develop from preexisting benign mixed tumors. Just exactly at what point during this gradual transition a given growth should be classified as benign or malignant is difficult to specify. Since the morphologic composition of a series of tumors of the major salivary glands is so variable, the five year cure rate cannot be stated with certainty. It may be said, however, that in those tumors regarded as histologically malignant by the pathologist a 40 to 50 per cent five year cure rate may be expected with proper treatment.

In large tumor clinics it is found that about 50 per cent of patients with parotid tumors (both benign and malignant) give a history of inadequate surgical removal before admission. Even in these, the rate of cure with proper treatment should be relatively high. The dangers of such incomplete removal are (1) that later extension of the growth or subsequent surgical treatment may cause permanent injury to the facial nerve and (2) that over a period of years with repeated recurrences a benign tumor may become malignant.

VI. CANCER OF THE PARANASAL SINUSES

The paranasal (nasal accessory) sinuses consist of the paired maxillary antrums, ethmoids, sphenoids and frontal sinuses. This system of air-filled structures intercommunicate with one another and with the middle meatus of the nasal cavity.

When cancer occurs in the mucosa of these spaces or their extensions, the growth progresses toward and tends to extend into the nasal cavity. In a large proportion of cases more than one of the sinuses are involved. Tumors originating in the ethmoid cells tend to grow forward toward the nasal cavity and antrum, laterally into the orbit or backward into the sphenoids. When cancer of the maxillary sinus arises on the mesial and upper walls, there is frequently invasion of the ethmoids, so that it is often difficult to determine the exact anatomic site of the origin of the tumor. Growths of the frontal sinus occur so rarely that for practical purposes they may be disregarded in this discussion. Similarly, the frontal sinuses do not often become involved secondarily by extension from tumors of other paranasal sinuses.

Malignant tumors of the paranasal sinuses occur with relative infrequency, comprising about 0.2 per cent of all human cancer and about 3 per cent of cancer in the upper respiratory and alimentary tracts. Growths in this locality are encountered more often in males (65 per cent) than in females, and in the age group of 60 to 70 years; the median age is 54 years.

There are no known causative factors for this disease. Although one might expect such lesions as chronic sinusitis, hypertrophic changes in the mucosa and polyps to precede the formation of cancer in this region and possibly contribute to its etiology, no acceptable evidence has been advanced to support such a causal relationship.

PATHOLOGY

As with most forms of cancer in the upper respiratory and alimentary tracts, the predominant morphologic variety found in the paranasal sinuses is epidermoid or squamous carcinoma. This is to be expected, since the nasal accessory sinuses are lined with a pseudostratified columnar type of epithelium. Occasionally, adenoid cystic carcinoma arises in this area. Anaplastic carcinoma, spindle cell sarcoma, lymphosarcoma and malignant mucoepidermoid tumors are but rarely encountered in this region. There are numerous distinct morphologic varieties of benign and malignant neoplasms that occasionally involve the nasal accessory sinuses secondarily by extension, such as osteogenic sarcoma, ossifying fibroma, juvenile nasopharyngeal fibroma, adamantinoma and epidermoid carcinoma or adenocarcinoma originating in the nasal cavity, gum or hard palate.

SYMPTOMS, MORBID ANATOMY, AND CLINICAL COURSE

There is practically only one initial symptom in cancer of the paranasal sinuses—namely swelling, usually occurring externally in the cheek, floor of the orbit or bridge of the nose. If the growth arises in the floor of the antrum, swelling will often appear in the hard palate, the alveolar ridge or the gingival buccal gutter. Ordinarily, there is little pain or discomfort in the early stages. The second most frequent symptoms are nasal obstruction and a bloody discharge from the nose.

The occurrence of swelling (asymmetry) in the cheeks or palate as the initial symptom in cancer of the paranasal sinuses is always significant, since it indicates that in practically all cases the growth has already invaded bone at some point in order to have reached the subcutaneous tissues. In cancer of the ethmoid such erosion may occur in the nasal wall of the orbit, displacing the eye outward. When the floor of the orbit is the seat of tumor invasion, the eyeball is elevated with unilateral exophthalmos. Erosion of the anterior or nasal walls of the antrum is associated first with swelling of the cheek and nasal obstruction and later with enlargement of the hard palate and obliteration of the gingival buccal gutter.

As the disease progresses and a greater portion of the maxilla becomes invaded by tumor, enlargement of the face becomes considerable, with pronounced displacement of the eye. There is often associated cellulitis and sepsis. Eventually, death occurs mainly from local extension of the disease. Metastasis usually occurs during the late stages of the disease when the local growth has not been controlled, and seldom becomes an important clinical problem in the treatment of cancer of the nasal accessory sinuses. In fatal cases the patient usually succumbs from the local effects of the disease before metastasis becomes manifest.

TREATMENT

The surgical excision of the paranasal sinuses has always been regarded as a difficult and hazardous procedure. Complete removal of the frontal, ethmoid and sphenoid sinuses is practically impossible, since this procedure would involve the sectioning of a portion of the base of the skull. Extirpation of the antrum can be accomplished by total excision of the maxilla, including the floor of the orbit. For these reasons radiation therapy has been widely employed for many years in the treatment of cancer of the nasal accessory sinuses. The results from this method of treatment, however, have been disappointing.

Cancer-lethal doses of radiation in this region will invariably produce serious complications, such as ocular edema, panophthalmitis and edema of the mucous membranes of the nasal cavity with obstruction to drainage and pansinusitis. Like all surface cancers, growths arising in the mucosa of the paranasal sinuses are ulcerated and infected from the beginning, and when drainage is blocked suppuration must occur. For this reason radiation therapy, even though it may sterilize the cancer, is so frequently followed by pansinusitis and sepsis that wide surgical exposure and drainage are required eventually. If the latter procedure is to be adequate, it must be of such scope as to be a little short of a radical resection; in many cases the latter procedure would have been sufficient to effect permanent control if used in the beginning.

From past experience and a review of the literature, one cannot escape the conclusion that the salvage rate in cancer of the paranasal sinuses is disappointing and the complications of cancer lethal radiation in this region almost always call for radical surgery. These considerations certainly suggest a greater resort to radical surgery in the beginning with an attempt to remove the tumor completely, or, failing that, to provide adequate drainage and assure sufficient removal of the growth so that radiation therapy can be more effectively applied. Such a surgical approach to the problem with a greater degree of safety to the patient has been made possible since the advent of chemotherapy, antibiotics, blood banks, improved surgical and anesthesia technics and recent advancements in the problems of nutrition.

If the growth is confined to the antrum, especially at the floor and in its lower portion, wide resection of the maxilla can be carried out with little risk to the patient. If the floor of the orbit is involved by tumor, the operation should include exenteration of the orbit, since removal of its bony floor is commonly followed by herniation of the orbital contents. When the growth extends into the ethmoids or sphenoids, these structures can be thoroughly curetted. In brief, it seems reasonable to attempt the widest possible excision of the growth and to use radiation therapy later, usually through the maxillary defect, in the event that recurrences take place.

PROGNOSIS AND END RESULTS

Since cancer of the paranasal sinuses produces symptoms only after erosion of bone and extension into the nasal cavity or soft parts of the cheek or orbit, the growth is usually well advanced when the patient first seeks medical advice, that is, several centimeters in diameter with extension into the contiguous structures. From the standpoint of early diagnosis, the outlook is poor, since early cancer in these areas is silent in its symptoms, in contrast to growths in such areas as the lip, anterior portion of the tongue and vocal cords. As has already been mentioned, both radiation therapy and surgical treatment have been limited and hazardous in this particular region—radiation therapy because of its complications and surgical treatment because of the impossibility of an extensive resection at the base of the skull.

No figures have been published as to the over-all cure rate (all comers) in cancer of the nasal accessory sinuses. At the Memorial Hospital, the most recently calculated five year cure rate, both surgical treatment and radiation therapy being used, with the main and primary reliance on surgical treatment, is about 13 per cent.

Clinical Notes, Suggestions and New Instruments

RISK OF UREMIA DUE TO SODIUM DEPLETION

WILLIAM B. MACGUIRE JR., M.D.
Brooklyn

It would be unfortunate if the comments of Allen[1] were widely interpreted as minimizing the risks inherent in sodium depletion. While it is true that observations of a large requirement of sodium and a dramatic rise of the level of blood urea in patients with nephritis who receive a diet restricted in sodium are somewhat unusual,[2] less rapidly developing, but equally dangerous, changes occur not infrequently when sodium depletion is employed routinely for congestive cardiac failure and for hypertension.

The case histories noted herein are only 3 of the many which have impressed me with the importance of observing the levels of blood urea or creatinine in any patient receiving such treatment.

Report of Cases

CASE 1.—R.M., a 38 year old bookkeeper, entered the hospital because of impaired vision of the left eye, which had occurred suddenly six days previously and had persisted until admission. He had relatively good health until this occurrence and then experienced anorexia, mild nausea and belching without hiccoughing, with one episode of vomiting on the night prior to entry. Nocturia, with urination on an average of three times during the night, had been present for an indefinite period.

Physical examination revealed blood pressure of 230 systolic and 160 diastolic, grade 4 hypertensive retinopathy, with a particularly large hemorrhage in the left fundus, the heart enlarged to the sixth intercostal space, with a gallop rhythm and a soft systolic murmur at the apex, and moist rales at the base of both lungs.

Examinations of the urine repeatedly yielded albuminuria (2 to 3 plus), occasional granular casts, red blood cells and white blood cells. The specific gravity was fixed at 1.011 and 1.012, and the hemoglobin varied from 9 to 11 Gm. A teleroentgenogram of the chest visualized an enlarged heart with congestive changes.

Because of the signs of mild congestive cardiac failure, the patient was given a Kempner diet (sodium 200 mg. per day). In addition, four injections of meralluride ("mercuhydrin sodium solution"), 2 cc., were given during the second week of hospitalization.

The blood urea, which was 37 mg. per hundred cubic centimeters (creatinine 1.9) on admission, rose steadily during the ensuing two weeks to a level above 200 mg. (creatinine 3.8), at which time the patient became clinically uremic and exhibited pericardial friction, which persisted for two and a half weeks. The urea remained at the elevated level for another week, at which time a regular diet was given. This was accompanied with an immediate and striking fall in the level of blood urea; by the end of the week it had fallen to 134 mg. per hundred cubic centimeters (creatinine 2.4) and the patient had improved.

The urea levels were followed up intermittently thereafter; two months later it was 44 mg. (creatinine 2.2) and another month later 87 mg. per hundred cubic centimeters (creatinine 2.1). However, during these months there was a steady downhill course, in which the patient experienced several episodes of cardiac failure (left); severe secondary anemia developed, and he died seven months after his first admission.

CASE 2.—B.S., a 57 year old Russian widow, entered the hospital because of symptoms of mild congestive cardiac failure. She had had diabetes mellitus for twenty-five years, requiring a maximum of 75 units of insulin in 1925; this amount was steadily diminished during later years, until on admission she was maintained free of urinary sugar without insulin. Hypertension, with the pressure above 200, was known to have existed since 1931. Two episodes of pyelitis or pyelonephritis had occurred. A gynecologic operation, presumably a complete hysterectomy, had been performed at the age of 22, a year following which she had reached her maximum weight of 300 pounds (about 136 Kg.).

For approximately one and a half years there had been progressive deterioration of vision, not improved with spectacles, and for the same period mild to moderate dyspnea on exertion, with several episodes of paroxysmal nocturnal dyspnea. It was because of a mild exacerbation of the latter that the patient sought admission. She now weighed 178 pounds (about 81 Kg.), and the blood pressure, which had been 170 systolic and 88 diastolic, fell to 120 to 140 systolic and 80 diastolic within one week and remained at that level. There was grade 3 retinopathy and an enlarged heart, with signs of mild congestive failure. Significant laboratory tests revealed a urinary output of fixed specific gravity, with 1 plus albuminuria and an occasional white blood cell and granular cast, and moderate secondary anemia, with a hemoglobin content of 8 Gm. A roentgenogram of the chest showed an enlarged heart with mild congestive changes. A roentgenogram of the skull revealed generalized hyperostosis, predominantly of the frontal and occipital bones. The basal metabolic rate was plus 1 per cent. Urinary ketosteroids were within normal limits. The glucose tolerance curve was normal.

Because of the signs of congestive failure a diet low in salt content was employed. However, by the ninth day the blood urea (90 mg. per hundred cubic centimeters on admission) had risen to 220 mg. and weakness and diarrhea had developed. On the eleventh day a diet containing 20 Gm. of protein and 9 Gm. of salt was given. The urea fell to 150 mg. after fourteen days of the high salt and low protein regimen and reached 85 mg. per hundred cubic centimeters after thirty-five days.

CASE 3.--Mrs. M.M., a 70 year old Scotswoman, entered the hospital because of an exacerbation of symptoms of congestive cardiac failure. Previous hospitalization had revealed a mitral valvular lesion, with auricular fibrillation associated with a patent intra-auricular septal defect. Hypertension (210 systolic and 140 diastolic and 180 systolic and 110 diastolic) had been noted on two previous admissions; with a regimen of bedrest and sodium depletion the blood pressure fell in the course of several weeks to 110 systolic and 80 diastolic and 138 systolic and 84 diastolic, respectively, paralleling improvement in the congestive failure, although it had been observed repeatedly that she had little cardiac reserve. At no time had a level of blood urea above 24 mg. per hundred cubic centimeters been noted. Examination of the urine had revealed a low specific gravity; with a trace of to 1 plus albumin and an occasional red blood cell seen microscopically. Examination at

the time of this entry revealed a blood pressure of 150 systolic and 90 diastolic, which fell to 130 systolic and 80 diastolic, and the signs of severe congestive failure.

The patient was again given a sodium depletion regimen, including mercurial diuresis, the house staff having taken into account previous responses and a level of urea of 40 mg. per hundred cubic centimeters on admission. Some improvement was noted, but the patient never again reached the ambulatory state. After three weeks of treatment the patient was noted to have become weak, anorexic, nauseated and drowsy. Two determinations of blood urea at this time were above 160 mg. per hundred cubic centimeters. She was given 9 Gm. of salt in the next twenty-four hours and 4 Gm. a day thereafter. Within six days the urea had fallen to 40 mg., and was only 50 mg. per hundred cubic centimeters several weeks later. The dosage of salt was lowered when the signs of congestive failure increased, but, despite efforts to maintain a balance in sodium administration, there was a steadily downhill course, and the patient died of cardiac failure about one month after her uremic episode.

Conclusions

The 3 cases reported herein (case 1, with malignant hypertension; case 2, with Morgagni-Moore-Morell syndrome and renal insufficiency secondary to either intercapillary glomerulosclerosis or chronic pyelonephritis with nephrosclerosis, and case 3, with rheumatic valvular disease, probably with nephrosclerosis) demonstrate the variety of diseases in which uremia may be encountered as a response to sodium depletion. It is again emphasized that these are not at all infrequent occurrences and that, in order to avoid such consequences, it is wise to watch carefully the levels of blood urea (or creatinine) in all patients on a sodium depletion regimen, especially in those in those in the older age groups and in those in whom renal disease is suspected or known to exist.

SEVERE ACUTE RENAL INSUFFICIENCY WITH RECOVERY

E. E. MUIRHEAD, M.D.
and
C. S. FROMM, M.D.
Dallas, Texas

Transurethral prostatectomy, with water as the irrigating fluid, is associated with prominent intravascular hemolysis, following which acute renal insufficiency develops in a proportion of cases.[1] This syndrome of acute renal insufficiency has been given various designations, such as the "renal anoxia syndrome,"[2] "lower nephron nephrosis"[3] and "hemoglobinuric nephrosis."[4] It has become apparent that the syndrome may result from a multiplicity of other causes, among which may be included prolonged hypotension (the shock state),[5] incompatible (hemolytic) blood transfusion reactions,[6] crush injuries,[7] carbon tetrachloride poisoning,[8] uteroplacental damage[9] and certain infections.[10] The clinical picture and renal lesions are similar, regardless of the causative background. An outstanding feature of this syndrome has been the high rate of mortality.

The methods of treatment for this condition have varied. The occasional spontaneous recovery in isolated cases has for some time demonstrated the reversible nature of the process involving the kidneys. Various forms of artificial measures for clearing waste products from the body have been attempted as means of sustaining patients through the critical period, until the kidneys initiate sufficient function once more. These artificial measures include gastric lavage,[11] peritoneal irrigation,[12] a combination of peritoneal irrigation and gastric lavage[13] and an artificial kidney for in vivo dialysis.[14] Renal decapsulation has been advocated by some[15] and rejected by others.[16] In reported cases generalized subcutaneous edema and pulmonary edema have been frequently mentioned complications. More recently, pleas for a con-

servative consideration of the fluid intake in these cases have been expressed.[17]

The clinical course in patients with the acute renal insufficiency syndrome (lower nephron nephrosis) lends itself well to a division into three phases, namely: (1) the phase of renal damage, during which hypotension is frequently present, (2) the phase of renal insufficiency and (3) the phase of diuresis. The various features of these phases have been discussed elsewhere.[18]

The renal lesions are characterized by damage to renal tubules, which is reflected microscopically by degeneration and focal necrosis. The distal segment of the nephron apparently sustains the greatest damage. Regeneration and recovery of these tubules become evident after about eight to ten days and are well advanced in twelve to fourteen days. It is of correlative interest that patients sustained through these intervals usually recover.

The belief has been expressed that the high rate of mortality of the past seems due to the type of management[19] and that a type of treatment based on the main abnormalities exhibited during each of the three phases can reduce the rate to low levels. This conclusion was originally expressed[1c] following treatment in 11 cases of severe disease with the "three phase" management. At the present time the series includes 20 cases of severe renal insufficiency so managed by one of us (E.E.M.) The 2 fatalities resulted from diffuse damage to the brain demonstrated in autopsies.[1c] The 2 patients had entered the phase of diuresis, thus indicating satisfactory progress of the renal disease.

In the case herein presented the disease was severe, and the satisfactory recovery affords additional support to the expressed contention. There were several unique features involved. The patient was a paraplegic war casualty with a cord bladder. Hemoglobinemia was observed following the transurethral resection of a small amount of bladder neck tissue to improve drainage. Water was used as the irrigating fluid during the operation. Pyelonephritis was known to be a complicating condition. Since the patient had no sensations, no anesthesia was given. No blood or other fluids were administered during the operation. Therefore, except for the pyelonephritis this was a case of acute renal insufficiency following transurethral resection, that is, one without the possible complication of blood transfusion reaction or anesthesia.

REPORT OF A CASE

E.P., aged 33, had had a cord injury, with complete functional transection of the spinal cord in the lower dorsal area, while in the military service. A suprapubic cystostomy had been performed while he was in the army, but the incision had been healed for many months. He was admitted to the Veterans Hospital (Dallas) because of pain, swelling and redness at the site of the old cystostomy incision. Urine drained through a small sinus in the incision, but this sinus healed when a urethral catheter was left in for a few days. The old wound would reopen and drain whenever the catheter was removed. After cystoscopic examination it was decided to resect the bladder neck. Complete anesthesia from the costal margin down existed, and no anesthetic was needed. On May 9, 1947, the patient was allowed a light breakfast and was taken to the operating room after receiving 1.5 grains (0.1 Gm.) of pentobarbital sodium. No fluids of any sort were given intravenously during the operation. There was no difficulty in passing the 28 F McCarthy resectoscope, and 3 to 4 Gm. of tissue was easily removed. A slight amount of oozing of blood was easily controlled with the Foley bag. The patient left the operating room in good condition, with no bleeding. On being returned to the ward and being placed on his bed he stated that he felt a little chilly, but had no other complaints. One hour later the patient was in severe shock, with systolic blood pressure of 50 and diastolic pressure of 30 mm. of mercury, rapid and almost imperceptible pulsations, cyanosis and dyspnea. There had been no irrigation. The urine from the catheter was bloody in appearance, and irrigation was promptly started. There were no clots in the bladder and the catheter was not obstructed. It was thought at first that the patient was bleeding, and he was immediately returned to the operating room. While typing and crossmatching for transfusion were carried out, 500 cc. of normal plasma was given. The resectoscope was reinserted, but there were no bleeding points or clots in the bladder. It was then noted that the serum from the blood sample for the transfusion tests was dark red. Subsequent blood samples likewise demonstrated prominent hemoglobinemia. It was realized that the patient had had a hemolytic reaction of the type described by Creevy and Webb,[1] due to the distilled water used during resection. A transfusion of 1,000 cc. of blood and 1,000 cc. of 5 per cent dextrose in water was given, and the blood pressure rose to within normal limits in two hours. The patient was restless and cyanotic for the first few days, and hiccoughs developed, which persisted for ten days. With a closed irrigating system the bladder was continuously irrigated. The fluid remained slightly bloody at all times. Because of the irrigation, there was no record of the urinary output for the first three days. The first measure of urinary output was 60 cc. on the fourth day. Subsequently, all twenty-four hour volumes of urine were obtained by catheter and accurately measured.

The charts and the table depict the progress in this case. On the second day hyperbilirubinemia was definite (elevated serum bilirubin and icterus index), thus confirming the hemolytic episode. A severe grade of renal failure developed. The renal insufficiency was characterized by decided oliguria, sharp and prominent eleviation of blood nonprotein nitrogen and urea concentrations, decrease in the carbon dioxide combining power of plasma and decrease in the concentrations of blood chloride and serum sodium. The urine samples were of low specific gravity and contained a low concentration of urea, varying between 13 and 23 per cent of normal. The plasma protein concentration was moderately depressed, but remained near the same level throughout the course. The urinary urea output was negligible for ten days. After the fourth day the urinary drainage had a purulent appearance, but this cleared when the volume of urine subsequently increased.

[19] Maegraith, Havord and Parsons.[2] Lucke.[3]

Treatment in this case was in accordance with the previously described "three phase" management.[1c] For the hypotension (shock state) of the first phase and the subsequent anemia that developed, blood transfusions were given. A total of 4,500 cc. of blood was given in eight days, 2,000 cc. being given during the first forty-eight hours. Initially, while blood was procured, 500 cc. of plasma was given. The following steps were observed during the second phase (renal insufficiency): (1) An attempt was made to maintain the state of hydration near normal, and an overload of salt and water was stringently averted; (2) the fluid allowed by mouth was given as a high caloric formula and as fruit juices; vitamin B complex was given parenterally, and, thus, complete starvation was prevented, and (3) the tendency toward acidosis was checked with sodium bicarbonate given by mouth.

The fluid-salt balance in this case posed a special problem not encountered in the earlier cases.[1c] Treatment was in May and June, which in Texas meant a relatively high environmental temperature. It was therefore considered that the daily insensible water loss and visible sweating amounted to 1,500 to 2,500 cc. (plus or minus). Diarrhea developed, and the stools were sufficiently liquid to be measured in volume. A rectal tube was inserted, and the liquid stools were collected. Moreover, edema of the paralyzed lower limbs became definite. With diarrhea, sweating and paralytic edema, the effective salt loss was increased over that in former cases. Therefore, an amount of salt greater than the urinary loss was given early (table). During the period of prescribed salt intake (fourth to fifteenth day) the salt loss by urine and stools was estimated to amount to over 100 Gm. The oral salt intake during this period amounted to 56 Gm. of sodium chloride and 66 Gm. of sodium bicarbonate. As the diuresis developed, toward the latter part of this period, and the patient exhibited clinical signs of extracellular fluid deficit, additional salt and water were given by vein (total of 59 Gm. of sodium chloride and 25 Gm. of sodium bicarbonate). It therefore follows that, with the losses through the urine, stool, skin and paralytic edema, the instituted salt therapy can be estimated to have approached a balance. This thinking applied at that time seems as reasonable in retrospect. It should be pointed out that, as on previous occasions,[1c] about half of the sodium bicarbonate was given to combat hyponatremia and acidosis. The latter is an empiric measure which seems to have merit. The apparent effectiveness of this measure was demonstrated by the elevation of the concentration of serum sodium and the maintenance of the carbon dioxide-combining power at the lower limits of normal.

Not only was there pronounced hyponatremia

but also prominent hypochloremia. The dilution of these two ions in the extracellular compartment has been a constant observation in the syndrome of acute renal insufficiency. In the present case this abnormality was apparently aggravated by the salt loss via the bowels and the skin. The dilution of these ions occurs, however, even in the absence of such an outward exit. This hypotonicity cannot be ascribed to fluid dilution, as it can be observed in patients obviously exhibiting extracellular water deficit.[18] Internal ionic shifts, of a poorly understood nature, must be the basis for this abnormality. Moreover, this abnormality seems directly related to the renal insufficiency, as the return of these ions to normal concentration parallels the return of the renal function (fig. 1 and fig. 2).

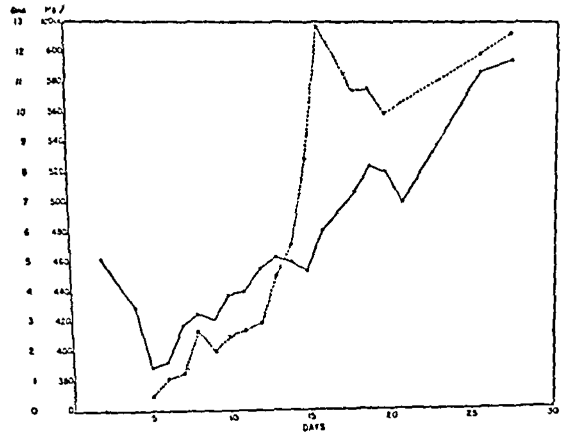

Fig. 1.—Chart showing determinations of urea in the blood (represented by the unbroken line, in milligrams per hundred cubic centimeters) and in the urine (represented by the unbroken line, in grams).

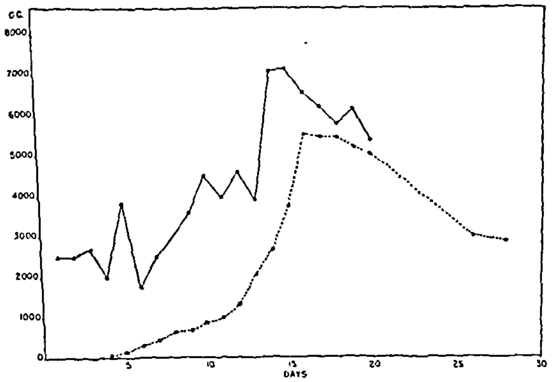

Fig. 2.—Chart showing the total intake of fluid (represented by the unbroken line) and the output of urine (represented by the broken line)

No positive measure was taken to lower the concentration of the blood urea and other accumulated wastes. Experience has indicated that the improvement of renal function occurs before these concentrations and the general backlog reach levels of an irreversible degree. In most cases the hypochloremia was not so severe as in this case, and no attempt was made to combat it as in this instance.

As on former occasions, no attempt was made to force the kidneys to produce urine. Attempts to replace the estimated daily water-salt loss (fig. 3 and fig. 4) were instituted, and renal regeneration was allowed to proceed without "prodding." There was no provision for weighing this patient, and during the second week a moderate extracellular water deficit (dry mouth, dry tongue, ropy saliva, dry skin and softened eyeballs) developed. This irregularity was rectified and did not appear to alter the improvement of the patient. The success of this regimen was attested to by the steady improvement of renal function followed by prominent diuresis and recovery.

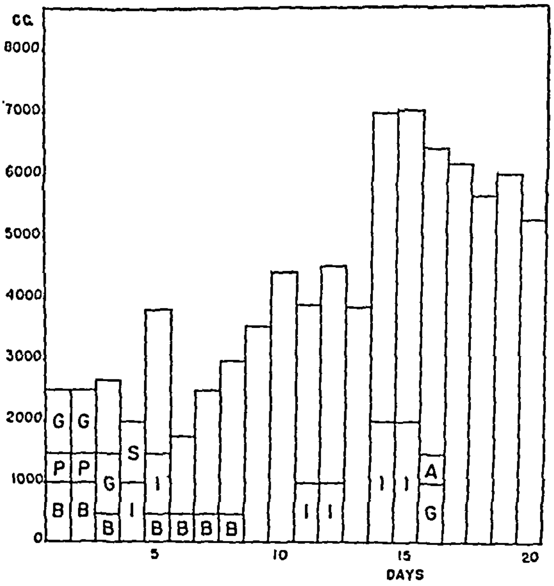

Fig. 3.—Chart showing the administered amounts of plasma (P), blood (B), sodium bicarbonate (I), 5 per cent "amigen solution" (a hydrolysate of casein prepared by digestion with porcine pancreas) (A), isotonic solution of sodium chloride (S), dextrose (G) and fluid by mouth (unlabeled part of bars).

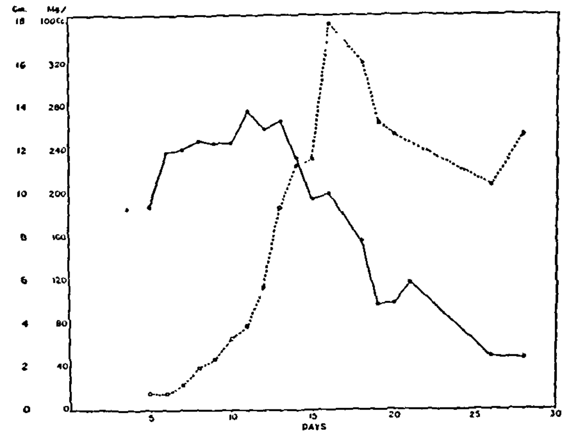

Fig. 4.—Chart showing determinations of sodium chloride in the plasma (represented by the unbroken line, in milligrams per hundred cubic centimeters) and in the urine (represented by the broken line, in grams).

During the diuresis the regimen of water-salt replacement was continued. The peak of the diuresis occurred on the sixteenth day, or later than in the average case (twelve and four-tenths days), as previously noted.[1c] Delayed diuresis has been noted in patients with a salt overload or with prior chronic renal damage. Thus, the chronic pyelonephritis may have accounted for the delayed diuresis. Certainly the combination of two renal complications tends to make for severer renal insufficiency.

On the sixteenth day a transient complication occurred. Sudden and decided gaseous distension developed. An enema and intramuscular injections of pituity ("pitressin") were given. The patient became weak and cyanotic. He was placed in an oxygen tent and given 7.5 grains of aminophylline intravenously. Large amounts of flatus and water were expelled, and improvement was immediate.

After the sixteenth day, with improvement of the appetite, the patient was able to adjust the water-salt intake himself. Recovery from renal insufficiency occurred satisfactorily. As of the time of writing, the patient had been followed up for ten months and was well so far as the renal function was concerned.

COMMENT

Acute renal damage with acute renal insufficiency is an entity which is not uncommonly encountered in a variety of conditions.[18] It is becoming apparent that the high rate of mortality ascribed to this condition in the past resulted mostly from the management. A water, water-salt, or salt intake far exceeding the capacity of the damaged kidneys has been frequently reported.

A high degree of success has been attained even in cases of severe disease with a regimen based on the main changes of the three phases of this syndrome. The first phase is frequently associated with hypotension, and blood transfusions have been given during this period. For hemorrhagic or severely anemic disease multiple transfusions may be required (2 to 4 liters or more, depending on the hemostasis and their factors). If blood is not available, plasma or albumin solutions may be used, but care should be taken not to overdilute the circulating red blood cells.[20] During the second, or renal insufficiency, phase, three main steps have been practiced: (*a*) A near normal state of hydration has been maintained by administered daily fluids equal to an estimated insensible loss (1,000 cc.) plus the volume equal to the urinary output; (*b*) the fluid has been given as a formula having roughly 1 calory per cubic centimeter, and (*c*) advanced acidosis has been averted by the use of sodium bicarbonate (4 to 6 Gm as indicated). No attempt has been made to force the kidneys to produce urine, and no attempt has been made to reduce the level of blood urea. During the third, or diuresis, phase water and salt have been replaced as indicated by the urinary output. The patients have been allowed early to regulate their own dietary and water-salt intake.

With this regimen it has not been necessary to resort to artificial measures, as peritoneal irrigation or in vivo dialysis. The dangers of peritoneal irrigation[12e] seem greater than those of this regimen. The ability of the kidneys to recover has been gratifying.

The complication of pyelonephritis in the case herein reported may have delayed the peak of the diuresis to the sixteenth day. Ordinarily there is no prominent avenue for the outward loss of salt, yet hypochloremia and hyponatremia develop. In the present case outward salt loss did occur, and it became necessary to institute active intake of salt during the renal insufficiency. The tendency toward acidosis is constant in this disease. It appears to be worth while to combat more advanced acidosis with a guarded intake of sodium bicarbonate (4 to 6 Gm. as indicated by the plasma bicarbonate concentration).

SUMMARY AND CONCLUSIONS

A case of severe acute renal insufficiency ("lower nephron nephrosis") is presented. Recovery was satisfactory with a regimen based on the main abnormalities of the three phases of this syndrome. Artificial measures for removal of waste products were not instituted and, for the period involved, did not seem indicated.

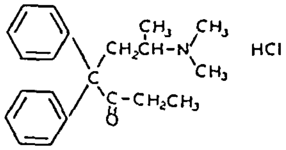
Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., *Secretary.*

METHADON HYDROCHLORIDE. Adanon-Winthrop-Stearns.--6-Dimethylamino-4,4-diphenylheptanone-3-hydrochloride.--$C_{21}H_{27}NO\ HCl$.--M. W. 345.90. The structural formula may be represented as follows:



Actions and Uses.—Methadon hydrochloride possesses, in general, a pharmacologic action similar to that of morphine. It is claimed that methadon causes less nausea and emesis, except when given orally, and less respiratory depression than morphine, with minimal analgesic doses. As a preanesthetic agent methadon is inferior to morphine, since it is not a sedative.

Methadon hydrochloride has definite addiction liability. After its prolonged administration withdrawal symptoms have appeared; however their onset is more gradual, they reach their peak more slowly, and their maximum intensity is less than after similar administration of morphine. Methadon can be substituted for morphine to prevent or alleviate morphine withdrawal symptoms.

Methadon hydrochloride may be used as an analgesic agent for the relief of moderate to severe pain. It is not recommended for conditions in which the sedative effects of morphine and related drugs are of importance. The drug has a satisfactory pertussive action.

---

[20] It is preferable not to allow a dilution beyond, 50 per cent.

Dosage.—Adults, 2.5 to 10 mg. depending on the intensity and nature of the pain. The usual dose is 7.5 mg. orally every three to four hours. For nonproductive cough, 1.25 to 2.5 mg. orally every three hours will usually be satisfactory.

Intramuscular injection is undesirable, but subcutaneous administration in doses of 2.5 to 10 mg. will usually be effective.

Tests and Standards

Methadon hydrochloride occurs as colorless crystals or as a white crystalline powder, odorless and possessing a bitter taste. It is soluble in water, freely soluble in alcohol and in chloroform, practically insoluble in ether and insoluble in glycerin. It is much more soluble in diluted sulfuric acid than in diluted nitric acid, but it is insoluble in diluted hydrochloric acid. It is incompatible with alkaline solutions and with syrup of wild cherry, U.S.P. It is precipitated from solution by the common alkaloidal reagents. The *pH* of a 1 per cent aqueous solution of methadon hydrochloride is between 4.5 and 6.5. It melts at 232-235 C. An aqueous solution of methadon hydrochloride, 30 mg. per 100 cc., exhibits an ultraviolet absorption maximum at 2,920 Angstrom units ($E^{1\%}_{1cm.} = 15.6 \pm 0.1$).

Dissolve about 0.1 Gm. of methadon hydrochloride in 10 cc. of water and add a clear, filtered solution of 0.125 Gm. of picrolonic acid dissolved in 50 cc. of boiling distilled water. Stir the mixture until the yellow precipitate is well formed. Allow the mixture to stand for 2 hours. Filter and recrystallize the residue from diluted alcohol. Filter and dry the residue: the product melts at 160-162 C.

Dissolve about 10 mg. of methadon hydrochloride in 2 cc. of water. Add 2 cc. of methyl orange T.S.: a yellow precipitate forms.

Dissolve about 10 mg. of methadon hydrochloride in 10 cc. of water, add 1 cc. of diluted nitric acid and 1 cc. of silver nitrate T.S.: a white precipitate forms which is soluble in excess ammonia T.S.

Dry about 1 Gm. of methadon hydrochloride, accurately weighed, for 24 hours at 100 C.: the loss in weight does not exceed 0.3 per cent.

Ignite about 0.1 Gm. of methadon hydrochloride, accurately weighed: the residue does not exceed 0.1 per cent.

Transfer about 0.5 Gm. of methadon hydrochloride, accurately weighed, to a 250 cc. flask and dissolve it in 50 cc. of water. Titrate with tenth-normal silver nitrate, using 10 drops of dichlorofluorescein T.S. as the indicator. Each cc. of tenth-normal silver nitrate corresponds to 3.546 mg. of chloride: the amount of chloride found is not less than 10.0 per cent nor more than 10.5 per cent, calculated to the dried substance. Transfer about 0.1 Gm. of methadon hydrochloride, accurately weighed, to a suitable Kjeldahl flask and determine the nitrogen content by the semimicro method (U.S.P. XIII, p. 672): the amount of nitrogen found is not less than 3.95 per cent nor more than 4.15 per cent, calculated to the dried substance.

Dissolve about 0.15 Gm. of methadon hydrochloride, accurately weighed, in 50 cc. of water in a separator. Add 20 cc. of ammonia T.S., and extract the methadon base with four successive portions of 40 cc., 20 cc., 20 cc., and 15 cc. of ether. Combine the ether extracts in a beaker and carefully evaporate the ether on a water bath in a stream of warm air. Dissolve the residue in 15 cc. of neutralized alcohol and titrate the solution with fiftieth-normal hydrochloric acid using methyl red T.S. as the indicator. Near the end of the titration add 50 cc. of water. Each cc. of fiftieth-normal hydrochloric acid is equivalent to 6.92 mg. of methadon base. The amount of methadon base found corresponds to not less than 88.5 per cent nor more than 90 per cent, calculated to the dried substance.

Tablets:

Weigh a counted number of not less than 20 methadon hydrochloride tablets and reduce them to a fine powder without appreciable loss. Weigh, accurately, a portion of the powder, equivalent to 30 mg. of methadon hydrochloride, and transfer it completely to a separator with the aid of 10 cc. of water. Make alkaline with 5 cc. of sodium hydroxide T.S., and mix well. Extract the methadon base with six successive 20 cc. portions of ether, filtering each ether extract through a pledget of cotton previously wetted with ether. Wash the separator and filter with 10 cc. of ether and add the washings to the filtered ether extracts. Wash the combined ether extracts with four 5 cc. portions of water, then extract the combined water extracts with 10 cc. of ether and add this ether extract to main ether extract. Extract the combined ether solution with exactly 20 cc. of hundredth-normal hydrochloric acid, followed by three 10 cc. portions of water. Warm the combined acid and water extracts on a water bath until the odor of ether is no longer perceptible. Cool and titrate the excess acid with hundredth-normal sodium hydroxide, using methyl red T.S. as the indicator. Each cc. of hundredth-normal hydrochloric acid is equivalent to 3.459 mg. of methadon hydrochloride, $C_{21}H_{27}NO \cdot HCl$: the amount of methadon hydrochloride found corresponds to not less than 93 per cent nor more than 107 per cent of the labeled amount of methadon hydrochloride.

Syrup, Elixir and Solutions:

Transfer to a separator an accurately measured volume of the syrup, or solution, equivalent to 30 mg. of methadon hydrochloride, and add 10 cc. of water. Follow the extraction procedure as directed in the assay of methadon hydrochloride tablets, beginning with, "Make alkaline with 5 cc. of sodium hydroxide T.S." The amount of methadon hydrochloride found corresponds to not less than 93 per cent nor more than 107 per cent of the labeled amount of methadon hydrochloride.

ABBOTT LABORATORIES, NORTH CHICAGO, ILL.

Solution Methadon Hydrochloride: 10 mg. per cc. 1 cc. ampuls. Each cubic centimeter contains 10 mg. of methadon hydrochloride in isotonic solution with sodium chloride.

Solution Methadon Hydrochloride: 10 mg. per cc. 20 cc. vials. Each cubic centimeter contains 10 mg. of methadon hydrochloride in isotonic solution with sodium chloride. Preserved with 0.9 per cent benzyl alcohol.

Tablets Methadon Hydrochloride: 2.5 mg, 5 mg. and 7.5 mg.

WINTHROP-STEARNS, INC., NEW YORK

Elixir Adanon Hydrochloride: 5 mg. per 5 cc., 473 cc. bottles.

Solution Adanon Hydrochloride: 5 mg. per cc., 2 cc. ampuls and 10 mg. per cc., 20 cc. vials.

Syrup Adanon Hydrochloride: 0.33 mg. per cc., 473 cc. bottles.

Tablets Adanon Hydrochloride: 2.5 mg., 7.5 mg. and 10 mg.

U. S. trademark, 435,101.

ESTRONE-U.S.P. (See New and Nonofficial Remedies 1947, p. 341).

The following additional dosage form has been accepted.

ELI LILLY & COMPANY, INDIANAPOLIS

Aqueous Suspension Estrone: 1 mg., 2 mg., 5 mg. per cc., 1 cc. ampuls.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following reports. HOWARD A. CARTER, *Secretary.*

G-E VARIABLE FREQUENCY WAVE GENERATOR ACCEPTABLE

Manufacturer: General Electric X-Ray Corp., Electromedical Section, 4855 McGeoch Avenue (W), Milwaukee 14, Wisconsin.

The G-E Variable Frequency Wave Generator is a device intended for use in stimulating denervated muscle for the prevention of atrophy. It is housed in a console-type case that can be moved about on casters. The case measures 58 by 53 cm. (23 by 21 inches) and stands 112 cm. (44 in.) high. It weighs 103 Kg. (227 lbs.); the shipping weight is 113 Kg. (250 lbs.). It operates on 110 to 120 volt 60-cycle alternating current, and the maximum power consumption is 525 watts, corresponding to approximately 5 amperes at 110 volts. It is equipped with 1 pair color coded electrode cords; 1 felt disk electrode 38 mm. (1.5 inch) diameter; 1 felt button electrode - 13 mm. (0.5 inch) diameter; 1 electro-diagnostic handle; 1 handle for disk electrodes; 1 ground cord extension - 3 meters (10 feet) long; 1 dispersive electrode - 10 by 15 cm. (4 by 6 in.); 2 dispersive electrodes - 5 by 7.5 cm. (2 by 3 in.); 1 dispersive electrode - 15 by 20 cm. (6 by 8 in.), and 1 dispersive electrode - 20 by 30 cm. (8 by 12 in.).

For direct current the ripple does not exceed 0.15 per cent. The maximum output with 2,000 ohms resistance is 100 milliamperes, which is essential for all therapy or diagnosis utilizing direct current.

For sinusoidal current the deviation from the pure sine wave was plus or minus 2 per cent. The frequency of the sinusoidal current can be varied progressively from a range of 2 to 6,000 cycles per minute or 0.033 to 100 cycles per second.

When the sinusoidal current is used for therapeutic and diagnostic purposes one recommendation is for treatment of denervated or partially denervated muscle. These muscles require a wide range of frequencies for the varying stages of muscle irritability, namely, two cycles per minute to forty cycles per second (2,400 cycles per minute).

The longer the period of degeneration the lower the frequency required to stimulate the muscle with an unmodulated sinusoidal current. Thus, there are muscles that respond maximally to the very low frequencies of two per minute to one per second (60 per minute). This current is a sinusoidal current and hence should be so named. Each electrical cycle may produce two muscular contractions, one contraction for the positive phase, and another contraction for the negative phase.

Some muscles respond maximally to the higher frequencies, namely, from two to forty per second. When the frequency reaches a value of two cycles or more per second the resultant denervated muscle contraction is sustained and tetanic in character. Therefore, it is necessary to modulate this fundamental sinusoidal current in order to secure a graduated muscle contraction. The modulation is secured by means of a double sine wave and is at a rate of two to sixty per minute. This is an adequate range. In the opinion of the Council this form of the current should be termed a modulated sinusoidal current with carrier frequency of 2 to 40 cycles per second.

To stimulate the normal skeletal muscle the complete range of frequencies necessary extends from 40 to 100 cycles per second. At these frequencies the current must be modulated for the same reasons stated before. In the opinion of the Council this current then should be termed a modulated sinusoidal current with carrier frequency of 40 to 100 cycles per second. When and if a sustained tetanic form of contraction is desired, it can be secured by using a frequency of 40 to 100 cycles per second and eliminating the modulation control. This current is not a "Faradic" current, but physiologically it produces the same effects.

For diagnosis the intensity-frequency curve can be secured by plotting frequency on the horizontal axis, and current in milliamperes on the vertical axis. The current recorded is that strength required to secure the minimal muscle contraction at various frequencies.

The lower the frequency required for minimal current values, the greater the degree of degeneration. A muscle responding to a frequency of 15 cycles per second with a minimal current intensity has a better prognosis than one responding to a frequency of one cycle per second. As the muscle improves, there is a shift in the frequency requirement-it moves from a lower to a higher frequency range.

This apparatus is supplied with the following controls and meters:

1. A master switch, which also serves as the line switch, selects alternating or direct current and the proper meter as well as meter scale.
2. Stimulation frequency scales are provided, one graduated to 2 to 120 cycles per minute, the other to 2 to 100 cycles per second. The scale selection is made by means of a scale selector switch.
3. Contraction frequency control is provided with a scale graduated from 2 to 60 cycles per minute and an "On" and "Off" switch.
4. The a-c milliameter is provided with 1.5, 15, and 150 milliampere scales and reads peak values of the alternating current.
5. The d-c milliameter is provided with 20 and 200 milliampere scales.
6. The intensity control has an arbitrary 0 to 100 scale. It regulates the amount of current passing through the patient and incorporates a safety feature which assures that no current can flow to the patient unless the operator first places this control on zero position.

The receptacles into which the electrode cords are inserted are connected to a two prong twist lock plug.

The Council on Physical Medicine voted to include the G-E Variable Frequency Wave Generator in its list of accepted devices.

THE GYNOGRAPH ACCEPTABLE

Manufacturer: Goodman-Kleiner Co., Inc., 5 East 17th Street, New York 3, N. Y.

The Gynograph manufactured by the Goodman-Kleiner Co., Inc., is a device which makes it possible to inject measured volumes of liquid or gas, under controlled pressures into the uterus and uterine tubes; it is designed for use in tubal insufflations with carbon dioxide, in hysterosalpingography, and in viscerographic procedures such as pneumoperitoneum. It is arranged to utilize conveniently the small cartridges in which carbon dioxide is being sold at present. The gas expands into a pressure-reducing chamber, whence it can be led into cannulas or be used to force fluids like iodized oil into the passages connected with the uterus.

The apparatus is easily portable. It weighs less than 4.5 Kg. (10 pounds), and when it is in its case the over-all measurements are 40 by 19 by 18 cm. (15¾ by 7½ by 7 in.).

The Council on Physical Medicine voted to include the Gynograph in its list of accepted devices.

HOSPITAL SERVICE IN THE UNITED STATES

TWENTY-SEVENTH ANNUAL PRESENTATION OF HOSPITAL DATA BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS OF THE AMERICAN MEDICAL ASSOCIATION

The Annual Report on Hospital Service in the United States is based on census reports submitted by registered hospitals in the United States, Alaska, Guam, Hawaii, Puerto Rico, the Canal Zone and the Virgin Islands. Census blanks are distributed to all registered hospitals annually, and these form the basis for official listings of registered hospitals, hospitals approved for internship and residency training, approved technical schools, as well as for special studies. The reporting period may represent a calendar year or the latest twelve month period for which statistics are available. Compilation and correction of the data continue to date of publication.

SUMMARY OF HOSPITAL DATA—1947

All Registered Hospitals		General Hospitals	
Number	6,276	Number	4,539
Bed capacity	1,425,222	Bed capacity	592,453
Bassinets	86,378	Bassinets	82,303
Patients admitted	15,829,514	Patients admitted	14,665,195
Births	2,837,139	Births	2,756,959
Average daily census	1,217,229	Average daily census	456,761
Patient days	444,288,585	Patient days	166,717,765

The current report for 1947 contains: (1) the official list of hospitals registered by the American Medical Association in accordance with standards formulated by the Council on Medical Education and Hospitals as adopted by the House of Delegates, including symbols designating those hospitals approved for internship and residency training by the Council on Medical Education and Hospitals, hospitals approved by the American College of Surgeons as meeting unconditionally its minimum requirements for standardization, and hospitals conducting accredited schools of nursing; (2) statistical tables together with textual material covering various aspects of hospital service and related subjects; (3) lists and general information on technical schools approved by the American Medical Association in cooperation with the several agencies concerned, and (4) tables relating to nursing service and education. Information covering approved internships and residencies was published in an earlier issue, (The Journal, May 1, 1948).

The trend toward increased use of hospital facilities is reflected in tables which follow. Notwithstanding an appreciable drop in total capacity, admissions to registered hospitals increased; this increase occurred largely in the nongovernmental group. A striking increase occurred in the number of hospital births, with a record figure reported. A further trend is seen in the continued reduction in the average hospital stay per patient.

Compilation of the following data is possible only through the cooperation of the hospitals which are represented. For their generous support of this annual survey, the Council on Medical Education and Hospitals wishes to express its gratitude to the Surgeons General of the Army, Navy and United States Public Health Service, to the Air Surgeon and the Administrator of the Federal Security Administration, to the Medical Director of the Veterans Administration and to hospital administrators and others who have assisted in the preparation of this survey.

Scope of Survey

All hospitals registered by the American Medical Association are represented in the 1947 survey; they include civilian hospitals, those under the control of the Army and Navy, United States Public Health Service and other units of the Federal Security Agency, the Veterans Administration, as well as other governmental hospitals. Registration lists cover hospitals in the United States and the possessions; the latter group, however, is not included in the tabular data, which reflect the status of hospitals within the continental United States. In the registered group, 807 hospitals are approved for internship training and 1,102 for residency training in the specialties; the majority of the hospitals so designated have approval for both types of graduate training. A total of 2,609 hospitals appearing in the official list are accredited by the American College of Surgeons as meeting unconditionally its minimum requirements for standardization. Since changes and corrections are made in the official list of registration up to the date of publication, totals taken directly from this source may vary slightly from those presented in the tables.

TABLE A.—*Summary of Growth of Hospitals, 1909 to 1947*

	Federal Hospitals		State Hospitals		All Other Hospitals		Total	
Year	Number	Capacity	Number	Capacity	Number	Capacity	Number	Capacity
1909	71	8,827	232	189,049	4,056	223,189	4,359	421,065

TABLE B.—*Number of Hospitals According to Size*

Bed Capacity	General Hospitals	Nervous and Mental	Tuberculosis	Other Hospitals	Total Number
Below 25	988	30	25	142	1,185
26-50	1,083	85	78	205	1,451
51-100	977	71	125	182	1,355
101-200	788	46	94	110	1,038
201-300	322	31	17	41	444
Over 300	381	322	72	28	803
Totals	4,539	585	441	711	6,276

Number, Size and Classification of Hospitals

The number of registered hospitals, as compared with the previous year's report, remained about constant, with 6,280 registered in 1946 and 6,276 in 1947. There was a decrease of 45 hospitals in the governmental group, largely due to the continued drop in the number of federal hospitals reported. This loss was offset by a gain of 41 hospitals in the nongovernmental groups, representing increases in the nonprofit association hospitals and those controlled by corporations (profit unrestricted). While the federal hospitals continued to decrease in number, the decrease was relatively small as compared with the previous year's drop, when 241 less hospitals were reported. A summary of the changes in the number of registered hospitals and their bed capacities is found in table A, accompanying this text.

Table B gives a breakdown of registered hospitals on the basis of bed capacity. Relatively few changes occurred during the current period, as might have been expected in view of the relative constancy of the number registered. Hospitals of 100 bed capacity and under showed an increase from 3,969 to 3,991. Hospitals from 101 beds to 300 increased from 1,471 to 1,482, while hospitals of 301 bed capacity and over fell from 840 in 1946 to 803 in 1947; 34 of this 37 decrease was in the general hospital class. Tables C and D present summaries of hospital service from the standpoint of type of control and type of service primarily rendered. Governmental hospitals are classified on the basis of the political unit exercising control; nongovernmental are subdivided on the basis of incorporation as nonprofit or proprietary organizations.

Governmental hospitals declined in number from 1,962 to 1,917. This decrease occurred principally in the federally controlled group, which numbered 464 hospitals in the previous report and 401 in 1947; the city-county category also showed a decline, from 64 to 58. Total nonprofit hospitals increased by 24 during the reporting period and proprietary hospitals by 17, raising the total of nongovernmental units to 4,359, a gain of less than 1 per cent.

Little variation from last year's figures is observed in comparing the data based on type of service rendered.

Total all hospitals	6,276	1,425,222	1,217,229	86,378	2,837,139	15,829,514

Neuropsychiatric hospitals increased from 575 to 585, while tuberculosis sanatoriums decreased by about the same number, from 450 in 1946 to 441 in 1947. General hospitals showed a gain of 18 over the previous report, perhaps fewer than would be anticipated. When the decrease in the number of federal hospitals is considered, however, this apparently slight increase appears more significant. General hospitals account for 70 per cent of all hospitals registered, neuropsychiatric for slightly over 9 per cent, tuberculosis sanatoriums for 7 per cent, and the remaining number is made up of several categories including maternal, industrial, eye, ear, nose and throat, children's, orthopedic, isolation, convalescent and rest, institutions, and an inclusive classification, "all other hospitals." The official list classifies those registered as hospitals and sanatoriums, and related institutions.

Bed Capacity

Comparative Totals
1946: 1,468,714
1947: 1,425,222

From the high point of 1,738,944 beds reported in 1945, the bed capacity in registered hospitals has declined to its present level of 1,425,222 beds, representing a further decline of 52,529 beds in the governmental group, primarily federal hospitals, and an increase of 9,037 in the nongovernmental category. This compares with a loss of 273,984 beds in governmental hospitals, reported last year and a gain in nongovernmental hospitals of 3,754 beds for the same period. With federal hospitals as a whole reporting the decrease noted, the bed capacities of hospitals under Veterans Administration control gained slightly, with 102,235 beds reported as of July 13, 1948. City hospitals showed an increase of 1,650 beds; state, county and city-county institutions, on the other hand, indicated small decreases in their capacities. On the basis of currently available statistics, governmental hospitals now control 72.3 per cent of all hospital beds and the nongovernmental group 27.7 per cent; this compares with 73.7 and 26.3 in 1946 and 78 per cent and 22 per cent in 1945. It should be noted that 626,648 of the 1,030,205 beds under governmental control are located in state hospitals, largely of special types.

Table E.—*Governmental and Nongovernmental Hospital Service*

Total nongovernmental	4,359	395,017	312,626	70,654	2,395,557	11,625,170
Total all hospitals	6,276	1,425,222	1,217,229	86,378	2,837,139	15,829,514

The bed capacity of general hospitals continued to decline, with 641,331 beds reported in 1946 and 592,453 the past year. This decrease, however, should be interpreted in the light of the increase of beds in the nongovernmental group; these latter rose from a figure of 324,211 for 1946 to 334,569 in 1947. General hospitals now represent 41.6 per cent of all beds, neuropsychiatric hospitals 47.9 per cent, tuberculosis sanatoriums 5.8 per cent and other institutions 4.7 per cent. There was an appreciable gain in the number of neuropsychiatric beds during the period, from 674,930 to 680,913; this amounts to only about one third the gain shown in these hospitals during the 1945-1946 period, however. A condensation of data presented above is found in table E, Governmental and Nongovernmental

Hospital Service. Table F presents a complete statistical analysis from the standpoint of type of service and the agencies concerned, of the number of registered hospitals, their bed capacity, average daily census, number of bassinets and births, with total admissions to these hospitals.

Number of Patients Admitted

Comparative Totals
1946: 15,153,452
1947: 15,829,514

The trend toward increased use of hospital facilities is seen in the greater number of admissions to registered hospitals reported for 1947. Notwithstanding an appreciable drop in the bed capacity, 4.4 per cent more patients were admitted than during the 1946 period. If nongovernmental hospitals alone are considered, the increase is over 10 per cent. Excluding the federal hospitals, all other groups showed an increase in their rate. Admissions to nonprofit organization hospitals rose from 9,198,159 to 10,177,508, an increase of 979,349 patients; this category now accounts for 64.3 per cent of the total number of admissions. The federal hospitals reported a decrease of 664,585 in their admissions; neuropsychiatric hospitals and tuberculosis sanatoriums in the federal group, however, indicated 3 per cent and 22 per cent increases. Governmental hospitals, with 72.3 per cent of the bed capacity, had 4,204,344 admissions, or 26.5 per cent of the total; the nongovernmental hospitals, with 27.7 per cent of the beds, had 11,625,170 admissions, or 73.5 per cent. The

corresponding percentages in 1946 were 33 and 67. These statistics should be considered on the basis of the type of service involved. For example, federal hospitals of the general type, with 9.2 per cent of the total number of beds, admitted 7.4 per cent of the total number of patients, a more equable proportion. When the type of service offered is considered, increases were noted in practically all categories. General hospitals increased the number of patients admitted from 14,051,508 to 14,665,195, a gain of 613,687 patients. Appreciable decreases were noted only in admissions to the group classified as institutional, from 144,664 in 1946 to 140,276 in 1947; a part of this decrease may be accounted for by change of classification of the reporting unit. Admissions to tuberculosis sanatoriums remained about constant, with 99,741 admissions for the previous period and 99,080 this year.

Of every 1,000 patients entering hospitals during the current reporting period, 926 were admitted to general hospitals, 18 entered neuropsychiatric institutions, 14 were admitted to related institutions including convalescent homes, 10 to isolation units, 7 to eye, ear, nose and throat, 6 to tuberculosis sanatoriums, 6 to maternity hospitals, 6 to children's, 4 to industrial and 3 to orthopedic hospitals. In considering the total volume of hospital service rendered, it should be noted that outpatient activities and newborn admissions are not included in the accompanying charts and tables. Comparative data will be found in tables 1 and 2 and other tables accompanying the text.

Average Daily Census

Comparative Totals
1946: 1,239,454
1947: 1,217,229

Following the decrease in bed capacity, the average daily census for 1947 fell off by 22,225 patients. The decline in bed capacity, as previously noted, was 23,492. Again, the loss was restricted to governmental hospitals, with the federal group showing a daily census of 168,133 in comparison to 213,246 for 1946. The city-county category also showed a decrease, from 7,863 to 7,657. All other hospitals, governmental and nongovernmental, reported an increase roughly paralleling the rise in bed capacity. The governmental hospitals, with 72.3 per cent of the bed capacity and 26.5 per cent of the total admissions, had an average daily census of 904,603, or 74.3 per cent of the daily patient load in all registered hospitals. In the nongovernmental classification, the church and other nonprofit hospitals reported an average of 277,615, or 22.8 per cent, while the proprietary hospitals, with a census of 35,011, had 2.9 per cent of the patient load. The general hospitals as a group reported an average census of 456,761 as compared with 496,527 for 1946, including 191,676 in the government division and 265,085 in the nongovernmental hospitals. There was a reduction of 50,648 in the governmental general hospitals, with the federal group responsible for 45,113 of the decrease. Nongovernmental general hospitals, on the other hand, showed an increase of 10,882 in the average daily census, a figure closely approximating the rise in bed capacity. The average daily census in neuropsychiatric hospitals continued to rise, with an increase of 15,809 over

		Total	2,837,139

the previous year. Of the total number, 651,578, governmental hospitals reported 635,702 or 97.5 per cent and the nongovernmental 15,876 or 2.5 per cent. Federal hospitals showed an increase of 10,468, state institutions 3,995, county hospitals 653 and city hospitals 29. The average daily census in nongovernmental hospitals of this type remained about constant, 15,122 in 1946 and 15,876 in 1947. The neuropsychiatric hospitals have 42.1 per cent of the total number of beds and less than 2 per cent of admissions, but care for 52.7 per cent of the average daily patient load, as reflected by the daily census. Census figures indicate that there were on the average 53,102 patients in governmental type tuberculosis hospitals during the reporting period with an additional 9,473 in nongovernmental sanatoriums. This represents a minor increase of 644 patients over the 1946 figure, divided proportionately between the governmental and nongovernmental groups. No significant changes are noted in comparing average daily census figures for 1946 and 1947 in the other classifications, which account for less than 4 per cent of the total census figure.

Percentage of Beds Occupied

Comparative Totals
1946: 84.4
1947: 85.4

The accompanying table gives comparative data relating to bed occupancy for the past three years on the basis of hospital control and type of service. A slight rise, from 84.4 per cent to 85.4 per cent, is noted for the entire group. The range begins at 64.6 per cent in the individual and partnership group and rises to 93.5 per cent in state-controlled hospitals. Governmental hospitals as a group reported a percentage of 87.8, while that in the nongovernmental hospitals was 79.1. The difference between these figures is accounted for largely by the higher proportion of neuropsychiatric beds in the governmental category.

In considering bed occupancy from the standpoint of type of service, the range starts at 43.6 per cent for isolation hospitals, with the upper level 95.7 in the neuropsychiatric group. The comparatively low rate of admissions and long periods of hospitalization in the latter type of cases should be taken into consideration in evaluating these percentages. A range of 80 to 85 per cent probably represents the maximum limit of operating efficiency in a general hospital. Patient turnover, repairs, remodeling and reallocation preclude the possibility of a much higher proportion of beds being available. For practical purposes, a hospital indicating 80 to 85 per cent occupancy can be said to be operating at capacity. The low percentage of occupancy in the isolation group can be expected in view of the seasonal demand for beds of this type.

Average Length of Stay

Comparative Totals
1946: 12.9 days
1947: 11.4 days

The length of stay per patient in all general hospitals was reduced by 1.5 days from the 1946 average. The greatest reduction came in the governmental group, where a decrease of 2.6 days was noted. This reflects the reduced proportion of federal hospital beds, the stay in this type of hospital exceeding the other governmental classifications by 13.2 to 18.1 days. Nonprofit general hospitals reduced their average stay from 9.6 days to 9.0, while the proprietary general class showed a slight increase, from 6.3 in 1946 to 6.5 in 1947. Nongovernmental general hospitals continued their downward trend in this respect with the average patient remaining 8.7 days. The stay in governmental general exceeded that in nongovernmental hospitals by 10.8 days, and that in federal general hospitals exceeded the stay in the same group by 21.1 days. Comparative data for the past three years based on the type of control are given in detail in table H accompanying the text.

Births in Hospitals

Comparative Totals
1946: 2,136,373
1947: 2,837,139

A striking increase in the number of births in registered hospitals occurred during the 1947 reporting period. The 1946 report on hospital service indicated that, for the first time, hospital births reached the two million mark. Hospitals this year reported a total of 2,837,139 births, a record figure, representing an increase of 32.8 per cent. Births in governmental hospitals increased from 334,946 to 441,582 or 31.8 per cent; those in nonprofit association hospitals from 1,594,652 to 2,123,516, a gain of 33.1 per cent, and in the proprietary group from 206,775 to 272,041, or a 31.5 per cent gain. Over 97 per cent of the total hospital births reported occurred in general hospitals, with an additional 2.6 per cent taking place in maternity hospitals. Nongovernmental hospitals report over 84 per cent of hospital births, with the governmental group accounting for slightly less than 16 per cent. Complete statistics covering this aspect of hospital service is found in the accompanying table listing all reported births for the past three years and for the year 1929. The tremendous gain in the number of hospital births during the past 18 years is an outstanding example of the increased utilization of hospital facilities in the United States.

Nursing Service

A comparison of the data presented in the accompanying table on Nursing Personnel and Schools of Nursing with similar statistics for previous years, is of considerable interest. In 1941 there were 93,977 student nurses enrolled in accredited schools of nursing; a gradual yearly increase brought this figure to a peak total of 130,909 in 1945. In 1946 there was a decrease in the enrolment, and again in 1947 a further drop, to 94,133 students. There was also a slight drop in the number of accredited schools of nursing, from 1,229 to 1,212, during the past year.

On the other hand, it will be seen that the number of graduate nurses in hospital positions has continued to rise, with 167,354 reported in 1947, an increase of 20,752 over 1946. The classification General Duty Nurses, Full Time, accounts for 14,871 of this increase, and reference to the table Professional and Auxiliary Nursing Personnel will show that this increase was limited to nonfederal hospitals.

It was to be expected that the number of volunteer nurses' aides should continue to decrease, with 3,116 fewer reported in 1947. It is interesting to note that hospitals are making more and more use of those persons falling into the general classification of practical nurses and attendants, the figure for this group being 23,654 greater than in 1946.

HOSPITALS REGISTERED BY THE AMERICAN MEDICAL ASSOCIATION

The following list contains the names of 6,276 hospitals, sanatoriums and related institutions that are located in the United States and 124 in Alaska, Canal Zone, Guam, Hawaii, Puerto Rico and Virgin Islands. The list for each state is presented in two groups: (1) hospitals and sanatoriums, and (2) related institutions. The related institutions include infirmaries, nursing homes and other institutions designed to give certain medical and nursing care in an ethical and acceptable manner, without giving a full hospital service.

Registration is a basic recognition extended to all hospitals and related institutions in accordance with the requirements outlined in the Essentials of a Registered Hospital officially adopted by the House of Delegates of the American Medical Association in 1928 and revised in 1947. *Approval,* on the other hand, is a designation extended by the Council on Medical Education and Hospitals to certain registered hospitals which meet the requirements for internship, residency or fellowship training; approval is also extended by the American College of Surgeons to those hospitals which unconditionally meet its minimum requirements for general standardization.

KEY TO SYMBOLS AND ABBREVIATIONS

★ Approved for training interns by the Council on Medical Education and Hospitals. List with detailed information is sent on request.

+ Approved for residencies or fellowships in the specialties. List with detailed information is sent on request.

▲ Approved by American College of Surgeons as meeting unconditionally its minimum requirements for general standardization.

○ School of nursing accredited by state board of nurse examiners.

⊙ Affiliated for nurse training on state accredited basis.

† Figures for "average census" and "admissions" are exclusive of newborn infants.

The column headed "Type of Service" indicates the general categories of patients treated:

Card	Cardiac
Chil	Children
Chr	Chronic
Conv	Convalescent and rest
Drug	Drug and alcoholic
Epil	Epileptic
ENT	Eye, ear, nose and throat
Gen	General
Incur	Incurable
Indus	Industrial
Inst	Institutional
Iso	Isolation
Mat	Maternity
MatCh	Maternity and children
MeDe	Mentally deficient
Ment	Mental
N&M	Nervous and mental
Orth	Orthopedic
SkCa	Skin and cancer
TB	Tuberculosis
Ven	Venereal

The column headed "Control" indicates control, or auspices under which the institution is conducted:

GOVERNMENTAL

Fed	Federal
IA	Indian Affairs
Army	United States Army
Navy	United States Navy
USPHS	United States Public Health Service
Vet	Veterans Administration
State	
City	
County	
City-County	
CyCo	

NONPROFIT ORGANIZATIONS

Church	
NPAssn	Nonprofit Association

PROPRIETARY.

Indiv	Individual
Part	Partnership
Corp	Corporation (unrestricted as to profit)

Corrections were made in the list to the time of going to press. Totals of the list, therefore, may vary from totals in Tables 1 and 2 which were necessarily compiled earlier.
